Aberdeenshire, sanitary work in, 1097, 1682, 1907
Abney, Sir William, knighthood for, 43
Abortion, quacks and, 356, 510, 1297
Abraham, Dr. P., dermatographia, 710
Abrahams, Dr. B., chorea, 384
Abscess: of the heart, 315; of the brain (or cerebral), 388, 929, 1277; of the liver, 534, 556, 853, 1285; in connexion with the appendix, 541; cerebellar, 543; of the spleen, 710; in the pubic region, 710; gaseous, 1021; cerebral, threatened, 1277; of the pericardium, 1434; spinal, 1805
Absent-minded Beggar (review), 1663
Absorption, intestinal, 1084
Accidents, medical attendance for, 1336
Accouchements, La Pratique des (review), 711
Acetylene lamps for bicycles, 1482, 1566
Achondroplasia, 618
Acidity, 1, 393
Acne necrotica or varioliformis, 27; varioliformis, 238; vulgaris, combined with eczema, 385
Acromegaly (review), 1592
Acroparæsthesia, 1795
Actinomycosis of the kidney, 68; of the neck, 1210
Actions-at-law brought by medical men, 141, 341, 510, 635, 982, 1080, 1176, 1413, 1452; by an osteopathist against a board of health, 275; by a schoolmaster against a pupil, 632; against the Plumbers' Company, 638; against an unregistered dentist, 791; against the Prussian Treasury, 970; for breach of promise, 972; against a hotel company, 1017; against the *British Medical Journal*, 1296; for damages for antenatal injuries, 1336; against medical men, 1809, 1812; against a district council, 1877; against a hospital, 1916
Adams, Lieut.-Col. A., The Western Rajputana States (review), 171
Adams, Mr. W., the late, 402; obituary, 812
Adams *versus* the *British Medical Journal*, 1296
Addenbrooke, Dr. B., abscess in the pubic region, 710
Addison's disease with leucoderma, 453; following enteric fever, 1665
Adelaide, alleged cases of plague in, 657, 810; drainage of, 891
Adelaide Hospital, 1099
Aden, plague in, 639
Adenitis, chronic, of various glands, 1009
Adeno-carcinoma of the ear, 543
Adiposis dolorosa, 1803
Adulteration, when it is good, 177
Adulteration of golden syrup, 177
Adulteration (see also Food)
Advertisement, a suspicious, 212; puffing, by an unqualified practitioner, 743
Advertisements, improper, 355, 432, 744, 899, 900, 950; medical, in newspapers and popular periodicals, 744, 899, 1042; pernicious, 1042
Advertising mural, 1180
Æsculapius and his sanctuary, 1221
Africa, South, endemic hæmaturia in, 249; public health in, 581; tsetse fly in, 593; enteric fever in, 1740
Africa, South, war in, 56, 117, 182, 258, 334, 402, 483, 560, 639, 723, 794, 873, 956, 1026, 1088, 1151, 1237, 1308, 1382, 1460, 1535, 1606, 1676, 1742, 1818, 1899 (see also Army, Boers, Rhodesia Royal Army Medical Corps, Services, Sick and Wounded, Soldiers, Troops, War in South Africa, South African Zulus)
Africa, West, blackwater fever in, 11; floating hospitals for, 178; malaria expedition to, 871; the effects of service in, 952
Africa, West (see also Ashanti, Gold Coast, West African)
African horse sickness, virus of the, 1441
African travellers (see Livingstone)
After-care Association, 1131
Ages (see Middle Ages, Old age)
Agglutination of red corpuscles, the use of, for diagnostic purposes, 1210
Agglutination (see also Typhoid bacillus and typhoid fever)
Agraphia, 1446
Aid (see First-aid, Medical aid)
Ainley, Mr. D., obituary, 1331
Air (see Fresh air, Liquid air, Open-air)
Aitken, Dr. D. W., tuberculosis, 1447; tonsil clamp, 1664
Aix-la-Chapelle, the treatment of syphilis at, 542
Akenside, Mark, 1378
Alabone, the General Medical Council *versus*, 715
Albino, 543
Albuminuria in pregnancy, 169; the proteids excreted in, 853; Physiological (review), 1011
Albumosuria, 540
Alcohol, the prescribing of, *versus* our own interests, 89, 198; and the respiration, 478; as an antidote in carbolic acid poisoning, 481; the effect of, on the human brain, 956, 1271
Alcohol (see also Anti-alcoholic, Drink, Inebriates, Intoxicating liquors, Licensing laws, Spirit-bars, Temperance)
Alcoholic stimulants and life assurance, 630; diathesis, 861; neuritis, perforating ulcer of the foot in, 1224
Alcoholism, varieties and treatment of, 891; the "gold-cure" of, death of the author of, 971; and suicide, 1081; treatment of, 1473; acute, cortical hyperæsthesia in, 1739
Aldershot, deaths from heat at, 1842, 1920
Aldershot field day, 1737, 1812
Alderson, Dr. W. E., contraction of the hands, 388
Aldgate High-street, the slaughter-houses in, 431
Alexander, Mr. W. F., carbolic disinfectants, 158
Alexander, Maj. A. C. A., the late, 334; obituary, 351
Alexander, Dr. W., coal and pebbles in the vagina, 620; ophthalmia, 579, 940
Alexander, Mr. P. Y., Darwin and Darwinism (review), 944
Alexandria, the plague in, in 1899, 1534
Alford, Mr. H. T. M., presentation to, 278
Alive under the coffin lid, 661
Allan, Dr. C. M., lead poisoning, 966
Allbutt, Prof. T. C., A System of Medicine (review), 466
Allchin, Dr. W. H., A Manual of Medicine (review), 1887
Allen, Dr. W. J., embolism, 1074
Allingham, Mr. H., opening the pericardial sac, 693
Almanac (see British Almanac)
Alopecia areata, cases of, 386
Althaus, Dr. Julius, obituary, 1763
Althorp, Mr. C. F. M., sarcoma, 941; aneurysm, 1010; the liver, 1446
Ambulance, the use of the, in civil practice, 475; horse, in Manchester, 1034
Ambulance corps, Sir J. Sivewright's, 653; vehicles, military, 495, 728; wagons, 814; competition at Crewe, 1145; class, instructor for an, appeal for an, 1381
Ambulances, horse, 1604, 1768, 1816, 1836, 1907
Amenorrhœa, pathological, 939
America, the United States of, legal control of prostitution in, 328; marine hospital service of, 477; cancer in, 717; expedition of the Liverpool School of Tropical Medicine to, 1893
America, the United States of, and American (see also NEW YORK, CORRESPONDENCE FROM, Anglo-American, Spanish-American)
America, South, plague in, 69
America, South (see also Argentine Republic, River Plate, Paraguay)
American methods of dealing with plague, 629; medical degrees, valueless, 715; small-calibre bullets, 789; congress of tuberculosis, 1083; Neurological Association, 1605
Amido-butyric acid (β), injections of, the production of coma by, 706
Amyloform, 470
Amyloid sections, the mounting of, 381, 384; disease, the experimental production of, in animals, 384
Anæmia, splenic, 115; splenic, and diabetes, 401
Anæmia, pernicious, a chronic infective disease, 221, 296, 371; relapsing, 709; case of, 780; treated by antistreptococcic serum, 1198; and its pathology, 1602
Anæmia, case of, 239; oxygen in, 1003; the treatment of, by iron and arsenic, 1146
Anæsthesia, failure of respiration under, 1518, 1656
Anæsthesia, local, produced by eucaine, 928; the production of, in the ear, 1125
Anæsthesias, ether and other, sequelæ of, 29
Anæsthetic, "gas and oxygen" as an, 1435; management of the, in cases of respiratory impediment, 1714
Anæsthetics (review), 1661
Anæsthetics, the giving of, by unqualified persons, 283; for young children, the administration and choice of, 1211; persons dying under, coroners' inquests on, 1811, 1908
Anæsthetics, deaths under (see Chloroform, Ether)
Anæsthetist's position towards quack dentistry, 283
Analgesia, local, produced by eucaine β, 156, 1106
Analysis of Food and Drugs (review), 468
Analysts, public, qualifications of, 866

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.—Diabetic marmalade; Gerolstein natural mineral water; Bynoglycerophosphates; Saarburg Moselle; Urotropine; "Fino Puro" sherry; Mistura ferri salina; Fine old brandy (Spanish); Citrophen;

Cascara chocolettes; Maltzyme, 35—Various selected wines; London stout; Chloretone; Gluten bread and biscuits; New tabloids and Soloids; Oxydel, 105, 106—Malted marmalade; Amyloform; Keystone Burgundy (ferruginous); Special drugs (Merrell); "I and I" food; Kola Astier; Baking flour for making brown bread; Reeve's cocoa essence; Fluid extract of malt and glycerophosphates; Table jellies; Baking powder; "Mafuta" preserved bananas; Patent custards, 470, 471—Soloids of protargol; Valtine globules (medicated); Milkine food; Anti-asthmatic powder; V.V.O. Scotch whisky; Montague rose cream soap; Antikamnia codeine tablets; Tropon preparations and oatmeal cocoa; Invalid foods; Digestive food and biscuits, 1290, 1291—Tabloids quinine hydrobromide; Vibif fluid beef; Clarence fruit juice crystals; Mercurol; Champagne cider; Hyrgolum; Sacrette sugar; Lagrima, 1449, 1450—China tea; Drumalban whisky; Nao food preparations, 1522

Anatomy, Surgical (review), 1138
Anatomy and Physiology, Journal of (review), 241, 1289
Anatomy (see also Myology)
Anchovies, adulteration of, 49
Anders, Dr. J. M., Practice of Medicine (review), 782
Anderson, Dr. A. J., antistreptococcic serum, 315
Anderson, Mr. A. R., boric acid, 574; suprapubic prostatectomy, 1075
Anderson, Dr. J., Trousseau's wine, 898
Anderson, Mr. G. R., hernia, 940
Anderson, Mr. R., gastric ulcer, 944
Anderson, Dr. F., placenta prævia, 1660
Anderson, Dr. T. McCall, tuberculin, 1703
Anderson, Mr. R. B., midwives registration, 1088; corporate and medical reform, 1304
Anderson, Miss May, presentation to, 1102
Anderson and Fenner *versus* Moeller, 1413, 1452
Aneurysm, femoral, 461, 1074; subclavio-axillary, 463; popliteal, 463; of the aorta, 623, 710, 858, 1584; of the neck, 707; arteriovenous, of the cavernous sinus, 1010; abdominal, 1071; innominate, 1209, 1443; subclavian, 1285, 1284; axillary, 1365; thoracic, 1730
Aneurysmal varix, 622
Angina, the pronunciation of, 180
Anglo-American Insurance Company, 72, 271, 956 (see also Hopwood)
Angus, Mr. H. B., cases exhibited, 388
Angus, Dr., embolism, 1010
Anilin oil in aural surgery, 1125
Animals, Kindness to, Church Society for the Promotion of, 322; Experiments on (review), 391; Comparative Physiology and Morphology of (review), 1288
Animals, unsexing, the after-effects of, 866; living, experiments on, 1842
Ankle-joint, disease of, 1365
Annett, Dr. H. E., tubercle bacilli, 159; bacillus of pink-eye, 201; Malaria Expedition, &c. (review), 1010
Anophthalmos, 940
Antenatal life, the chronology of, 938; injuries, damages claimed for, 1336
Anthrax, the dissemination of, 44
Anthrax (or malignant pustule), cases of 136, 164, 1005
Anthropology (see Man, Races of)
Anti-alcoholic serum, 44
Anti-asthmatic powder, 1290
Anti-enteric vaccine, 665
Antikamnia codeine tablets, 1290
Anti-plague inoculation, 567, 713
Anti-pneumotoxin, 460
Anti-rabic Institute in Cairo, work of the, 503; in India, 1911
Antiseptic, a urinary, urotropine as, 1876
Antiseptics in food, the effect of, on digestion and dyspepsia, 507
Antistreptococcic serum in septic lymphangitis, 303; in puerperal septicæmia, 315; in pernicious anæmia, 1198; in septicæmia, 1591; in cerebro-spinal meningitis, 1897
Antitobacco league, 424
Antitoxin of cobra venom, 384
Antitoxin treatment of diphtheria, 138, 326, 943, 1030, 1093, 1167
Antityphoid inoculations, 150, 245, 338, 429, 504, 565, 967, 1477, 1478
Antivaccination, 1886
Antivaccination League and Dr. W. J. Collins, 134, 266, 332; propaganda, 423; tactics, 868
Antivaccinationists as vaccination officers, 740
Antivenomous serum, the standardisation of, 1433
Antivivisection, 1886
Antivivisection Bill in the United States, 583
Antivivisectionists and Mr. R. E. Lloyd, 665
Antral suppuration, 636
Antrum (see Mastoid antrum)
Aorta, aneurysm of the, 623, 710, 858, 1584
Aortas, atheromatous and dilated, 1209
Aortic valves, atheromatous endocarditis of the, 707; regurgitant murmur heard in the pulmonary area, 1282
Aphasia, motor, 940; sensory, 1446
Aphasic paralysis, the use of raised letters in, 1699, 1767
Apomorphine as a hypnotic, 1083, 1481, 1635
Apoplexy, heat, in the Argentine Republic, 868
Apostoli, Dr., the late, 1329
Apothecaries, Society of (see Society of, &c.)
Apothecaries' Hall, Ireland, pass list, 505; the examinations, the General Medical Council and, 1688, 1760
Appendicitis, a mode of operating in, 87; acute, operations for, 197, 264; pathology and treatment of, 225, 235, 557, 615; reflections upon, 294; prognosis in, 378; levurine in, 619; treatment of, without operation, 645, 1010; in pregnancy, 809; suppurative, 852; in a hernial sac, 1085
Appendix, abscess in connexion with the, 541
Appointments, weekly lists of, 70, 141, 209, 281, 353, 430, 508, 587, 665, 741, 815, 896, 979, 1040, 1104, 1177, 1254, 1333, 1412, 1479, 1563 1632, 1697, 1765, 1843, 1923
Appointments, various, some non-medical, 247, 402, 502, 579, 658, 664, 868, 882, 888, 893, 895, 954, 968, 1035, 1899
Appointments (see also Medical Appointments, Medical Magistrates, Services)
Archambault, Dr. J. L., empyema, 719
Archbold, Mr. W. A. J., Cambridge Appointments Association, 1543
Architectural Hygiene (review), 626
Area condemnation under the Housing Acts, 943
Argentine Republic, plague in the, 721, 737, 1022; heat apoplexy in the, 868
Argyle, Dr. S. S., milk, 891
Arithmetical triangle in ophthalmology, 1801
Arm, deformity of the, from fracture, 101
Armstrong, Mr. W., Buxton water, 1651
Army estimates, 729
Army in South Africa, dental surgeons for the, 486
Army medical corps, New South Wales, 811
Army, medical establishment of the, vote for the, 740, 894, 948
Army medical officer, reported murder of an, 572, the retired, the position of, 732, 886; a German, on the war in South Africa, 970
Army medical report for 1898, 1384, 1675, 1827
Army, medical organisation for the, 586
Army Medical School, Netley: pass lists, 62, 1320; the Indian Medical Service, 130; close of the session, 334; commencement of the session, 653; list of nominated surgeons, 729; surgeons on probation, 882, 964, 1029; an appointment, 882; close of the session, 1831
Army medical service in the field, lecture on, 205
Army medical service, the strength of the, 429
Army medical services, the Canadian, 1914
Army ration, the American, 137
Army recruits, the teeth of, 894
Army surgeons, Italian, memorial to, 889
Army veterinary department, report of the, 1532
Army, the United States, medical department of, reforms in the, 276; the French, conscripts for, 882; the Swiss, 970; the Italian, tuberculosis in, 1082; the French, typhoid fever in, 1172; the French, temperance measures in, 1472
Army (see also Frontier force, Reservists, Royal Army Medical Corps, Sick and wounded, Soldiers, Troops, War, Wounded)
Arnold, Mr. G. J., aneurysm, 1584
Arsenic, poisoning by, 407; hypodermic injection of, 899; in anæmia, 1146
Arsenic (see also Cacodyle)
Arterio-sclerosis, cardiac failure due to, mercury in, 1519, 1881
Arthritis, gonorrhœal, treatment of, 387; rheumatic, in a child, 457; rheumatoid, the excretion of nitrogen in, 706
Arthrodesis, 30
Arum maculatum, poisoning by, 1176
Ascites, hæmorrhagic, 17, 131; produced by fibroid tumour of the uterus, 30; lactescent, 869; chylous, 938, 1791; treatment of, 1045, 1262
Aseptic Surgery (review), 469
Ashanti, the situation in, 1397; colonial surgeons in, 1814
Ashby-de-la-Zouch Cottage Hospital, 1476
Ashford, Mr. W., presentation to, 1253
Ashmead, Dr. A. S., leprosy, 890
Assam, the unhealthiness of, 1321
Assistance Publique, the budget of the, 348
Assistant, the indoor, the accommodation of, 72
Assistants, qualified (or medical), the dearth of, 212, 355, 1293; unqualified, the employment of, 668
Associations, annual meetings (not including British Medical Association): Scottish Poor-law Medical Officers', 135; Manchester and Salford Sanitary, 578; Irish Workhouse, 808; Australian, for the Advancement of Science, 891; Western Counties Veterinary Medical, 893; Cornwall Nursing, 944; Dublin Sanitary, 1035; Asylum Workers', 1301; British Dental, 1749; British Medical Temperance, 1765
Asthmatic (see Anti-asthmatic)
Asylum reports, 123, 415, 1291, 1537, 1828; Workers' Association, 730, 1301, 1476; attendants up to date, 1250; pathology, 1444; workers, pensions for, 1527; superintendent, duties of a, 1672
Asylums, deficiencies in our, 806; modern, the construction of, 899; the Scottish, pathology at, 1020
Ataxy, Friedreich's, case of, 168
Athenæum Club, admission of Dr. W. S. Church, 871
Athletic Club, Bristol Medical, 428
Athletics, the effect of, on the heart and circulation, 174
Atkinson, Prof. J., and the cure of cripples, 211, 283
Atkinson, Dr. F. R. B., Acromegaly (review), 1592
Atkinson, Dr. J. M., carbolic acid in plague (see Erratum on p. 614)
Atmokausis, 1074 (see also Vaporisation)
Atmosphere, gases of the, 1813
Atropine in sea-sickness, 781; in plague, 1445
Atropine solutions, sterilisation of, 1173
Atropine (see also Homatropine)
Attwell, Mr. H., the Boers, 496
Auditory meatus, insects in the, 283; sensations in epilepsy, 1119
Auld, Dr. A., toxins of pneumococcus, 166
Aural surgery, the present position of, 359
Austen, Mr. E. E., Malaria Expedition, &c. (review), 1010

AUSTRALIA, CORRESPONDENCE FROM.—Health of Sydney, 138, 811—The standard of milk, 138—Small-pox on s.s. *Ninereh*, 138—Beriberi on board ship, 138—Appointments, 139—Plague, 427, 810, 1099, 1685—Annual meeting of the Victorian Branch of the British Medical Association, 427—New South Wales Nurses' Association, 427—Fever hospital at Sydney, 427—Surgeons for South Africa, 427—Primary sarcoma of the liver in a child, 427—Medical Society of Victoria, 811—New South Wales Army Medical Corps sent to South Africa, 811—Australasian Association for the Advancement of Science, 891—Adelaide Hospital, 1099—Prince Alfred Hospital, Sydney, 1099—Alleged breach of ethics, resignation of the council of the Victorian Branch of the British Medical Association, 1554, 1686—Sydney and Prince Alfred Hospitals, 1686—Memorial portrait of the late Sir Anthony Brownless, M.D., 1686

Australia, plague in, 427, 657, 810, 1023, 1081, 1099, 1223, 1297, 1377, 1459, 1470, 1548, 1679, 1685, 1758, 1836, 1908
Austria or Austrian (see VIENNA, CORRESPONDENCE FROM)
Austro-Hungarian war of 1848-1849 and the Boer war, 1604
Auto-intoxication, 1601
Axillary aneurysm, 1365
Ayr, typhoid fever in, 66, 202, 272, 347

B

Babtie, Maj. W., Victoria Cross awarded to, 1220, 1246, 1320
Baccelli, Dr. Guido, illness of, 503
Bacilli of diphtheria, non-typical, 942
Bacilluria, typhoid, 915, 1061

Mediastinal growths with secondary deposits in the spinal canal causing paraplegia, 1069; growths, the diagnosis of, 1145
Mediastinum, tuberculous glands in the, 1282, 1283
Medica (see Encyclopædia Medica, Materia medica, Bibliographia Medica)

MEDICAL SOCIETIES.

ÆSCULAPIAN SOCIETY.—Exhibition of cases, 544—Uterine carcinoma, 944—Micro-organisms in the causation of certain diseases of the nervous system, 1075—Pseudo-diphtheritic throat, 1213—Treatment of pulmonary tuberculosis, 1447—Use of mercury in the treatment of cardiac failure due to arterio-sclerosis, 1519, 1881
ANATOMICAL SOCIETY. — Meeting in Manchester, 1912
BECKENHAM AND PENGE MEDICAL SOCIETY.—The Cannon-street hotel meeting and Dr. Glover, 1755—Annual dinner, 1764
BERLIN MEDICAL SOCIETY.—Ladies as members, 273
BIRKENHEAD MEDICAL SOCIETY.—Peritonitis in the female, 316—General paralysis of the insane, 943—Dilatation of the stomach, 1212
BOMBAY MEDICAL AND PHYSICAL SOCIETY.—Atropine in plague; Diagnosis of typhoid fever and Malta fever, 1445
BOURNEMOUTH MEDICAL SOCIETY.—Cases of surgical interest, 1276
BRADFORD AND DISTRICT MEDICO-ETHICAL SOCIETY.—Election of officers, 240
BRADFORD MEDICO-CHIRURGICAL SOCIETY.—Contagion in modern times, 170—Inflamed corneal ulcers, 464—Exhibition of specimens, 941—Exhibition of cases, 1009—Exhibition of cases and specimens, 1445—Case of thoracic aneurysm; Uræmia, 1730
BRISTOL MEDICO-CHIRURGICAL SOCIETY.—Exhibition of specimens, 170—Intestinal obstruction, 452
BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—The treatment of diseases of the nervous system and nervous affections by baths and climate, 387—Treatment of nervous diseases by baths and climate, 943—The climate of Rhodesia, 1365—The hill stations of India as health resorts, 1659
BRITISH GYNÆCOLOGICAL SOCIETY.—Demonstrations by means of the kinematograph, 30—Annual meeting; Election of officers; President's valedictory address, 169—Chronic tubal inversion of the uterus, 464—Exhibition of specimens, 858—Exhibition of specimens; Uterine myoma removed by panhysterectomy; Treatment of cancer based on the parasitic theory, 1211—Indications for the removal of the uterine appendages, 1518—Exhibition of specimens; Indications for the removal of the uterine appendages, 1802
BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—Exhibition of cases, 314—Conditions of the throat and larynx simulating and predisposing to tuberculosis, 859—Use of the Roentgen rays in the diagnosis of diseases of the throat, nose, and neighbouring organs, 1591
BRITISH ORTHOPÆDIC SOCIETY.—Hallux valgus and varus and analogous deformities, 609, 621—Treatment of spinal abscess; Treatment of severe congenital equino-varus, 1805
CARDIFF MEDICAL SOCIETY.—Some points connected with the induction of premature labour, 171—Exhibition of specimens, 466
CHELSEA CLINICAL SOCIETY.—Treatment of rheumatism, 328, 761, 778, 872, 920, 933, 1016—Gynæcological therapeutics, 709—Valedictory address, 1886
CLINICAL SOCIETY.—Exhibition of cases, 167—Primary resection of gangrenous intestine; Primary abdominal section for wounds of the abdomen, 309—Cases of hæmo-pneumothorax; Perforated duodenal ulcer; Stricture of the small intestine following strangulated hernia, 458—Exhibition of cases, 617—The prevention of valvular disease in acute rheumatism, 776—Case of dermoid cyst within the spinal canal; Reduction of the deformity of spinal caries by manual rectification, 932—Exhibition of cases, 1282—Acute encephalitis following influenza; Operative treatment of gall-stones; Pneumothorax in an apparently healthy man, 1441—Case of gastro-enterostomy followed by pylorectomy; Septicæmia treated by anti-streptococcic serum and nuclein; Graves's disease, 1590
DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—Exhibition of cases, 315, 710, 1010, 1366—Annual meeting, 1381—Election of officers; The chief constitutional and local conditions associated with seborrhœa, 1660
EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases and specimens, 27—Salol in the treatment of small-pox; Permanent dislocation of the patella, 237—Hæmaturia; Increase of nervous disease and insanity, 461—Heredity in disease, 808—The effect of heredity on disease, 855—Laminectomy for paralysis; Activity of the saliva in diseased conditions of the body; "Cross infection" in fever hospitals; Exhibition of specimens, 1363—Exhibition of cases; Blood-pressure in sleeplessness and sleep; Origin, development, and structure of the umbilical cord, 1803
EDINBURGH OBSTETRICAL SOCIETY.—Vaginal cœliotomy, 28—Albuminuria, multiple pregnancy, papyraceous fœtus, and placenta prævia; Differentiation of connective tissue in the human fœtus, 169—Eclampsia; Basilysis; The use of levurine, 618—The chronology of ante-natal life; Double ovariotomy; Chylous ascites, 938, 1791—Vaporisation of the endometrium; Vulvar hæmatoma in labour, 1516—Exhibition of specimens; Nomenclature of transverse presentations and of version; Set of the pelvis in the body, 1885
EDINBURGH ROYAL MEDICAL SOCIETY.—Dinner, 808
EPIDEMIOLOGICAL SOCIETY.—Bacteriological diagnosis in a school epidemic of diphtheria, 236—Housing of the working classes in Liverpool, 482, 621—Measles, its distribution and control, 941—Infectivity of enteric fever, 1284—Changes in the council, 1519
FOLKESTONE MEDICAL SOCIETY.—Patent and quack remedies, 466—Musical evening, 859—Operative midwifery, 1286
FORFARSHIRE MEDICAL ASSOCIATION.—Exhibition of cases and specimens, 239—Nitrites and allied substances, 859—Exhibition of cases and specimens, 1213
FRENCH ACADEMY OF MEDICINE.—Election of a member, 502—Typhoid fever, 659—Disinfection after measles, 736—Influenza; Appendicitis, 809—Percussion of the cranium, 1036—Rabies, 1250—Sea-sickness, 1251—Malaria commission; The Tarnier bequest, 1405—Alcoholism, 1473—Facial neuralgia, 1616—Dissemination of small-pox by flies, 1761—Goitre, 1840—Disinfection of wells, 1913
FRENCH SOCIETY OF BIOLOGY.—Celebration of fiftieth anniversary, 204
FRENCH SOCIETY OF SURGERY.—New buildings, 273
GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—The involution of the puerperal uterus, 466
GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—Exhibition of cases and specimens, 315, 544, 1135
GLASGOW SOUTHERN MEDICAL SOCIETY.—Presentation, 1034
HARVEIAN SOCIETY.—Exhibition of cases, 101—Annual meeting, 239—Eye symptoms in the diagnosis of general diseases, 239, 287—Exhibition of cases and specimens, 384—Fibroid tumours of the uterus, 444—The feeding of infants with modified milk, 540—Suppression of urine, 541, 612—The localisation of cerebellar disease, 708—Exhibition of cases, 942—Discussion on the diagnosis and treatment of chronic purulent nasal discharges, 1073—Removal of a certain ring from the pharynx of a child; Congenital laryngeal obstruction; Cholesteatoma; Exhibition of cases, 1207—Selection of cases for abdominal section, 1446
HUNTERIAN SOCIETY.—Hunterian oration on the influence of modern surgery upon medical practice, 402, 1259—Election of officers, 781—Exhibition of specimens, 944—Some points in the therapeutics of gout, 1133—Exhibition of cases, 1658
IPSWICH CLINICAL SOCIETY.—Exhibition of cases, 543, 1010
ISLINGTON MEDICAL SOCIETY.—Midwives Bill, 872—Placenta prævia, 1660
KIDDERMINSTER MEDICAL SOCIETY.—Malformation of the vulva, 710—Exhibition of specimens; Double empyema, 1212
LARYNGOLOGICAL SOCIETY. — Exhibition of cases, 1135
LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Fœtid expectoration; Removal of a submucous fibroid by section of the uterus; Volvulus associated with hernia, 237—The notification of phthisis; The treatment of gonorrhœal arthritis, 386—Urotropine as a urinary antiseptic; Intestinal obstruction, 707—Exhibition of cases, 1007—"Return" cases of scarlet fever and th

length of infectivity of the disease; Simulation of gastric perforation; Exhibition of cases and specimens, 1133—Ventro-fixation; The pathology of gout, 1443

LEICESTER MEDICAL SOCIETY. — Centenary dinner, 650

LIFE ASSURANCE MEDICAL OFFICERS' ASSOCIATION.—Alcoholic stimulants, 630

LIVERPOOL MEDICAL INSTITUTION.—Fibroid tumour of the uterus, 30 — Election of officers, 170—The pathology and treatment of pneumonia; National Association for the Prevention of Consumption, 460, 579—Parasite of cancer; Exhibition of specimens, 541—Exhibition of cases, 620—Acute Bright's disease; Suprapubic lithotomy in old men with enlarged prostate; Bubonic plague, 783—Exhibition of cases and specimens, 858—Exhibition of cases, 940, 1074—Exhibition of specimens; The use of agglutination of red corpuscles for diagnostic purposes, 1209—Conversazione, 1249—Exhibition of cases; The so-called pulsus paradoxus, 1285

MANCHESTER CLINICAL SOCIETY.—Exhibition of cases, 30—The prevention of tuberculosis, 313—Exhibition of cases and specimens, 622, 1365

MANCHESTER MEDICAL SOCIETY.—Election of officers, 240—Presidential address, 544—Epididymectomy for tuberculosis of the right testis, 781—Rectal cancer and treatment by excision, 1135

MANCHESTER PATHOLOGICAL SOCIETY.—Exhibition of specimens, 239—Pathology of pneumonia, 544—Exhibition of specimens, 942—Pathological relations of the thyroid gland, 1213—Acute hæmorrhagic cystitis; Innominate aneurysm, 1443

MANCHESTER THERAPEUTICAL SOCIETY.—Mercuriol in syphilis, 709

MEDICAL SOCIETY OF LONDON.—Excision of the vesicula seminalis; Operative treatment of uterine fibroids, 99—Pathology and treatment of appendicitis, 225, 235, 378, 557, 615—Dinner, 402, 789—Exhibition of cases, 456—Lettsomian lectures on cancer of the breast, 684, 843, 990, 1094—New method of performing prostatectomy, 774—Coxa vara, 774, 1115—Chemistry of gout, 931—Exhibition of cases, 1071—Cystic diseases of the breast, 1201, 1206—24 years' death certificates in general practice, 1207—Conversazione, 1381, 1459, 1529—The causes of the first sound of the heart, 1430, 1440—Excision of the Gasserian ganglion for trigeminal neuralgia, 1440

MEDICAL SOCIETY OF VICTORIA. — Annual meeting, 811

MEDICO-PSYCHOLOGICAL ASSOCIATION. — Meeting of the Northern and Midland Division, 1102—General meeting, 1296—Meeting of the South-Eastern Division, 1332

MIDLAND MEDICAL SOCIETY.—Exhibition of cases and specimens, 314, 623, 780—Function of the pericardium, 1009

NEUROLOGICAL SOCIETY.—Annual meeting, 466

NEW CROSS MEDICAL SOCIETY.—Backache as a symptom of rectal disorder, 1128

NEW YORK ACADEMY OF MEDICINE.—Exhibition of cases, 1446

NEW YORK GENITO-URINARY SOCIETY.—Formation of the society, 1459

NEW YORK STATE MEDICAL SOCIETY.—Election of president, 662

NEWCASTLE-ON-TYNE CLINICAL SOCIETY.—Exhibition of cases, 388—The use of midwifery forceps, 465

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—Uterine fibroids, 147, 174—The open-air treatment of consumption, 102—Discussion on syphilis, 542

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—Minor gynæcology, 31—Exhibition of specimens, 315, 708—Treatment of fibro-myoma of the uterus, 1008—Exhibition of specimens; Prevention and relief of pain in minor gynæcology, 1366—Exhibition of specimens; The influence of gonorrhœa on the puerperium, 1731

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—Exhibition of cases, &c., 541

NORWICH MEDICO-CHIRURGICAL SOCIETY.—Professional union, 886

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—Cases of diphtheria treated by antitoxin, 943—Exhibition of cases and specimens, 1075

OBSTETRICAL SOCIETY.—Treatment of rupture of the uterus by packing the tear with iodoform gauze; Exhibition of specimens, 100—Annual meeting, 465—A lantern demonstration on the anatomy of two specimens of dropsical parasitic fœtuses; Extra-uterine gestation; Spondylolisthesis; Exhibition of cases and specimens, 777 — Incarcerated retro-displaced gravid uterus, 1072 — The relations of organic affections of the heart to fibro-myoma of the uterus; Exhibition of specimens, 1361—Extra-uterine gestation; Exhibition of specimens, 1729

ODONTOLOGICAL SOCIETY.—Grants in aid of research, 328, 555

OPHTHALMOLOGICAL SOCIETY.—Experimental exophthalmos and enophthalmos; Cicatrix horn growing from the cornea; Glaucoma following the use of homatropine, 310—Family tendency to ophthalmoplegia externa; Meningitis followed by panophthalmitis; Pigmented tumour of the eyeball; Green vision, 854—Opaque nerve-fibres remote from the disc degenerating after neuritis; Exhibition of cases and specimens, 1362—Occlusion of the central retinal artery on both sides; The arithmetical triangle in ophthalmology; Dermoid tumour of the conjunctiva; Periarteritis of the retinal arteries; Ophthalmitis associated with basal meningitis, 1801

OTOLOGICAL SOCIETY.—Position of aural surgery, 359—Cerebellar abscess, 542—Exhibition of cases and specimens, 857, 1515

OXFORD MEDICAL SOCIETY.—Clinical value of blood examinations, 544

PATHOLOGICAL SOCIETY.—The bacteriology of venous thrombi; Mycotic tumour from a horse; "Spontaneous" carcinoma; Experiments with the toxins of the pneumococcus, 165—The part played by insects in the spread of malaria; Experimental production of amyloid disease in animals; Neutralisation of cobra venom by its antitoxin; Cortical changes in acute chorea, 384—Discussion on the forms and significance of proteids in the urine, 539, 853—The results obtained by injecting β-amido-butyric acid into animals, 706—The changes of the blood in disease, 1006, 1360—Laboratory meeting, 1440, 1543—Exhibition of cases and specimens, 1589—Meeting at Cambridge, 1817

PLAISTOW AND CANNING TOWN MEDICAL SOCIETY.—Diphtheria, 623

READING PATHOLOGICAL SOCIETY.—Acidity, 1393

ROYAL ACADEMY OF MEDICINE IN IRELAND.—The examination of sick children, 28—Deciduoma malignum; Ulceration in the female urethra, 238 — Tracheotomy in diphtheria, 462—Protamines and their cleavage products, 619—Clinical report of the Rotunda Lying-in Hospital, 707, 1074—Presidential address; Infantile insanity, 856 — Growth of the typhoid bacillus; Exhibition of specimens, 939 — Congenital bullous eruption, 1007—Atmo-kausis and zesto-kausis, 1074—Polycoria; Thyroidectomy; Actinomycosis; Spinal dislocation, 1210; Chorea; Croup; Pemphigus and erythema, 1284 — Interscapulo-thoracic amputation; Axillary aneurysm; Disease of ankle-joint and foot, 1364—Commercial pepsin; Asylum pathology; The medico-legal relations of general paralysis, 1444—Sarcoma of both ovaries; Porro's operation, 1517—Tubal pregnancy; Pan-hysterectomy; Delivery of the placenta, 1730—Cerebro-spinal meningitis, 1805

ROYAL MEDICAL ACADEMY OF TURIN.—Cacodylate of soda, 1037

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Ophthalmoplegia externa, complicating Graves's disease; Action of tetanus toxin on nerve-cells of the cerebral cortex, 98—The mastoid operation for the cure of chronic purulent otorrhœa: methods and indications, 234—Discussion on mastoid operation for the cure of chronic purulent otorrhœa, 455, 576—Acute Ménière's symptoms in leucocythæmia, 615—Skin affections in Bright's disease, 773—Open-air treatment of tuberculosis, 870—Rupture of the œsophagus caused by vomiting; Sarcoma of the gastro-hepatic omentum, 930—The wounded in the present war, 1300, 1359, 1374, 1459, 1485, 1515—Alterations in the by-laws; The medical and surgical complications of pyorrhœa alveolaris, 1728—Innovations, 1895

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—Exhibition of microscopical and macroscopical specimens, 103—Report of the sanatorium treatment of phthisis at the Sheffield Royal Infirmary, 388—Exhibition of cases, 465—Exhibition of cases; Simple tonsillitis with paralysis of the soft palate; Cases of skin disease presenting unusual features, 781—Exhibition of cases and specimens, 940, 1075—Exhibition of cases and specimens; Cirrhosis of the liver in an infant, 1213

GREAT YARMOUTH GENERAL HOSPITAL.—A case of suppurative otitis; mastoid disease; cerebral abscess; necropsy (under the care of Dr. Henry Blake), 929
GUY'S HOSPITAL.—A successful case of removal of a packing-needle from the descending colon; rapid disappearance of intra-peritoneal adhesions (under the care of Mr. N. Davies-Colley), 96—A case of severe intra-uterine hæmorrhage from cystic molar pregnancy (under the care of Mr. J. H. Targett), 163
HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—A case of chronic intestinal obstruction; necropsy (under the care of Dr. D. E. Lees), 852
KENSINGTON INFIRMARY.—A case of traumatic tetanus with recovery (under the care of Dr. H. P. Potter), 705
KING'S COLLEGE HOSPITAL.—A case of chronic middle-ear suppuration with thrombosis of the lateral sinus in which the internal jugular vein was not ligatured; recovery (under the care of Mr. Arthur H. Cheatle), 96—A case of combined external and internal strangulation (under the care of Mr. Albert Carless), 1357—A case of pressure on the left bronchus; recovery (under the care of Dr. Norman Dalton and Dr. Greville MacDonald), 1438
LEEDS GENERAL INFIRMARY.—A case of rupture of the femoral artery (under the care of Mr. W. H. Brown), 539—A case of kyphotic pelvis (under the care of Dr. J. B. Hellier), 1279—A case of strangulated femoral hernia in which gangrene was precipitated by an intra-abdominal volvulus (under the care of Mr. R. Lawford Knaggs), 1726
LIVERPOOL NORTHERN HOSPITAL.—Ten cases of malignant pustule (under the care of Mr. Chauncy Puzey, Mr. Damer Harrisson, and Mr. R. W. Murray), 164
LIVERPOOL STANLEY HOSPITAL.—A case of retro-peritoneal fibro-cystic tumour; death from pulmonary embolism ten days after operation (under the care of Mr. D. Douglas-Crawford), 1514
LUCEA HOSPITAL, JAMAICA.—A case of prolapse of the rectum and a case of fibroids of the uterus (under the care of Dr. E. R. C. Earle), 1657
MIDDLESEX HOSPITAL.—A case of pregnancy complicated by fibrous tumour of the supra- and infra-vaginal cervix; abdominal hysterectomy; operation; recovery (under the care of Dr. William Duncan), 613
MONSALL FEVER HOSPITAL, MANCHESTER.—Two cases of perforation of the intestine during an attack of typhoid fever treated by laparotomy; one recovery (under the care of Dr. R. W. Marsden, medical superintendent), 1800
NEW HOSPITAL FOR WOMEN.—Three cases of intestinal suture (under the care of Mrs. Stanley Boyd, M.D. Brux.), 1586
NEW YORK POST-GRADUATE HOSPITAL.—A case of acute yellow atrophy of the liver (under the care of Dr. Stephen Smith Burt), 1438
NEWCASTLE-ON-TYNE ROYAL INFIRMARY.—A case of removal of a gall-stone from the common bile duct by the duodenal incision (under the care of Mr. Frederick Page), 1885
NORTHAMPTON GENERAL INFIRMARY.—A case of Addison's disease with associated leucoderma and tuberculous peritonitis (under the care of Dr. F. Buszard), 453
PENRHYN QUARRY HOSPITAL, BETHESDA.—A case of dislocation of the head of the tibia backwards, upwards, and inwards, and of the patella upwards and outwards (under the care of Dr. E. A. Mills-Roberts), 308
PRINCE ALFRED HOSPITAL, SYDNEY.—A case of strangulated inguinal hernia in an infant aged 14 days (under the care of Dr. Chas. MacLaurin), 1281
ROCHDALE INFIRMARY.—A case of intestinal obstruction arising from Meckel's diverticulum (under the care of Mr. R. B. Sellers), 383
ROTHERHAM HOSPITAL.—A case of meningitis following enucleation of the eyeball (under the care of Mr. F. B. Judge Baldwin), 772
ROYAL FREE HOSPITAL.—A case of compound separation of the lower epiphysis of the femur; recovery with useful limb (under the care of Mr. E. W. Roughton), 233
ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—A case of pyonephrosis with imperforate right ureter (congenital) (under the care of Mr. A. Marmaduke Sheild), 1131
ROYAL HOSPITAL, HASLAR.—A case of cerebral hæmorrhage presenting several unusual features; necropsy (under the care of Fleet Surgeon G. J. Irvine), 97
ST. BARTHOLOMEW'S HOSPITAL.—A case of suppression of urine associated with a single kidney (under the care of Mr. D'Arcy Power), 25
ST. GEORGE'S HOSPITAL.—Two interesting cases of hernia (under the care of Mr. G. R. Turner), 929—A series of cases of abdominal injuries without external wound treated by laparotomy (under the care of Mr. G. R. Turner), 1277—A case of hermaphroditism (under the care of Mr. G. R. Turner), 1884
ST. MARY'S HOSPITAL.—Two cases of resection for high rectal carcinoma (under the care of Mr. Page), 1004
ST. MARY'S HOSPITAL FOR SICK CHILDREN, PLAISTOW, E.—A case of diphtheria of the vulva (under the care of Dr. E. E. Ware), 382
ST. PANCRAS INFIRMARY.—A case of thrombosis of the superior mesenteric veins (under the care of Dr. W. M. Dunlop, medical superintendent), 1800
SHEFFIELD ROYAL INFIRMARY.—A case of traumatic tetanus with recovery (under the care of Dr. W. Dyson), 538
SOUTH DEVON AND EAST CORNWALL HOSPITAL.—A case of intestinal obstruction due to thrombosis of some of the mesenteric vessels; laparotomy; death; necropsy (under the care of Mr. C. Whipple), 705—A case of ovarian cyst communicating with thickened gall-bladder containing a solitary calculus (under the care of Mr. R. H. Lucy), 1132
SUSSEX COUNTY HOSPITAL.—A case of inter-scapulo-thoracic amputation (under the care of Mr. T. J. Verrall), 382
UNIVERSITY COLLEGE HOSPITAL.—A case of traumatic enopthalmos (under the care of Mr. Percy Flemming), 771
WESTMINSTER HOSPITAL.—A case of double optic neuritis from serous effusion (Quincke's disease) (under the care of Dr. W. Murrell), 1206—A case of lymphatic leukæmia or lymphocythæmia treated surgically by the the establishment of a collateral circulation (under the care of Dr. W. Murrell and Mr. Walter Spencer), 1725
WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—A case of suprapubic lithotomy; removal of two vesical calculi; recovery (under the care of Mr. T. Vincent Jackson), 26

Reservists, the families of, medical attendance on, 30
Respiration, alcohol and the, 478; Cheyne-Stokes, ocular phenomena associated with, 537; exalted, the production of glycosuria by, 706; failure of, under anæsthesia, 1518, 1656
Respiration (see also Tachypnœa, Pulsus paradoxus)
Respiratory affections, heroin in, 180; system, the after-effects of ether on the, 389, 557, 710, 779; jacket or waistcoat, 457; system in typhoid fever, 913; centre, paralysis of the, under chloroform, 1210; impediment, management of the anæsthetic in, 1714
Retina, the central arteries of the, occlusion of both, 1801
Retro-peritoneal fibro-cystic tumour, 1514
Revaccination, public vaccinators and, 252; a rapid result of, 1004

REVIEWS AND NOTICES OF BOOKS.

Encyclopædia Medica: under the general editorship of Chalmers Watson, M.B., M.R.C.P. Edin., 31, 1286—Laboratory Work in Bacteriology: by Frederick G. Novy, Sc.D., M.D., second edition, 31—Handbuch der Gynäkologie: edited by Professor Veit, 32—Text-book of the Embryology of Invertebrates: by Dr. E. Korschelt and Dr. K. Heider, 33—Atlas und Grundriss der Bakteriologie, und Lehrbuch der Speziellen Bakteriologischen Diagnostik: von Prof. K. B. Lehmann und Dr. R. O. Neumann, second edition, 33—Manual of Bacteriology: by Robert Muir, M.A., M.D. Edin., and James Ritchie, M.A., M.D. Edin., second edition, 34—Chemical and Microscopical Aids to Clinical Diagnosis: by C. C. Douglas, M.B., B.Sc. Edin., 34—Dictionnaire des Termes de Médecine (Français-Anglais): by H. de Méric, M.R.C.S. Eng., 34—System of Diseases of the Eye by American, British, Dutch, French, German, and Spanish Authors: edited by William F. Norris, A.M., M.D., and Charles A. Oliver, A.M., M.D., 104—The Hæmorrhages of Pregnancy, Parturition, and the Puerperium: the Treatment of Puerperal Eclampsia by Saline Infusions, with Notes of 17 Cases: by Robert Jardine, M.D. Edin., 105—The Western Rajputana States: a Medico-Topographical and General Account of Marwa, Sirohi, Jaisalmir: by Lt.-Col. Archibald Adams, I.M.S., M.D., M.Ch. R.U.I., F.R.C.S. Irel., 171—Diseases of the Eye: a Handbook of Ophthalmic Practice for Students and Practitioners: by G. E. de Schweinitz, A.M., M.D.; third edition, 172—Nursing: its Theory and Practice: by Percy G. Lewis, M.D. Brux., M.R.C.S. Eng., 172—Experimental Physics: by Eugene Lommel; translated from the German by G. W. Myers, 173—Practical Text-book of Midwifery for Nurses and Students: by Robert Jardine, M.D. Edin., 173—The Carlsbad Treatment for Tropical and Digestive Ailments and How to Carry it out Anywhere: by Louis Tarleton Young, M.D., B.Ch., B.A. Dub., Major I.M.S.; second edition, 173—The Pathologist's Handbook: a Manual for the Post-mortem Room: by T. N. Kelynack, M.D. Vict., M.R.C.P. Lond., 240—Lehmann's Medicinische Hand-Atlanten (Atlas of the Nervous System in Health and Disease): by Dr. Christfried Jakob; second edition, 240—Recherches Cliniques et Thérapeutiques sur l'Epilepsie, l'Hystérie, et l'Idiotie: par Bourneville, avec la collaboration de MM. Cestan, Chapotin, Katz, Noir, Phillippe, Sebilleau, et Boyer, 241—Dermato-histologische Technik: by Dr. Max Joseph and Dr. Georg Loewenbach, 241—A Pocket Medical Dictionary: by W. A. Newman Dorland, A.M., M.D., 241—Who's Who? for 1900, 241—Annual and Analytical Cyclopædia of Practical Medicine: by Charles E. de M. Sajous, M.D., 316—Raynaud's Disease: by

Thos. Kirkpatrick Monro, M.A., M.D. Glasg., 316—The Roentgen Rays in Medical Work: by David Walsh, M.D. Edin.; second edition, 317—L'Electricité en Physiologie: par M. Léon Morokhowetz, 317—Organic Chemistry: by W. H. Perkin., jun., Ph.D., F.R.S., and F. Stanley Kipping, Ph.D., D.Sc., F.R.S., 317—Elements of Practical Materia Medica and Pharmacy: by William Wood, M.B., C.M. Edin., 317—The Newer Remedies: by Virgil Coblentz, Ph.D., F.C.S.; third edition, 317—Progressive Medicine: a Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences: edited by Hobart Amory Hare, M.D., 389—The Races of Man: an Outline of Anthropology and Ethnography: by J. Deniker, Sc.D., Paris, 390—Experiments on Animals: by Stephen Paget, F.R.C.S. Eng., 391—A Manual of Surgery for Students and Practitioners: by Wm. Rose, M.B., B.S. Lond., F.R.C.S. Eng., and Albert Carless, M.S. Lond., F.R.C.S. Eng.; second edition, 391—The Use of Lead Compounds in Pottery from the Potter's Point of View: by William Burton, F.C.S., 391—Our Secret Friends and Foes: by Percy Faraday Frankland, Ph.D., B.Sc., F.R.S.; fourth edition, 392—An Introduction to Analytical Chemistry: by D. G. Henderson, D.Sc., M.A., F.I.C., and M. A. Parker, B.Sc., 392—The Year-book of Pharmacy, 1899, 392—Practical Hints on the Analysis of Water and Sewage: by Sidney Barwise, M.D. Lond., D.P.H. Cantab, 392—Examination of Water for Sanitary and Technic Purposes: by Henry Leffmann, A.M., M.D., Ph.D., 392—A System of Medicine by Many Writers: edited by Thomas Clifford Allbutt, M.A., M.D. Cantab., LL.D. Glasg., D.Sc., Vict., F.R.C P. Lond., F.R.S., vol. viii., 466—The Myology of the Pelvic Floor: a Contribution to Human and Comparative Anatomy: by Peter Thompson, M.D. Vict., 467—Cure Prompte et Radicale de la Syphilis; par le Dr. J. F. Larrien, 468—The Pharmacopœia of Guy's Hospital, 468—Merck's Manual of the Materia Medica, 468—Aids to the Analysis of Food and Drugs: by T. H. Pearmain and C. G. Moor, M.A., F.C.S., F.I.C.; second edition, 468—Synopsis of the British Pharmacopœia, 1898: compiled by H. Wippell Gadd, M.P.S.; fourth edition, 469—A Handbook of Nursing: by M. N. Oxford, 469—Aseptic Surgery: by Charles Barrett Lockwood, F.R.C.S. Eng.; second edition, 469—Golden Rules of Physiology: by I. Walker Hall, M.B., Ch.B. Vict., and Acworth Menzies, M.D., C.M. Edin., 469—The British Almanac for 1900, 469—Dod's Parliamentary Companion, 469—A Text-book of Diseases of the Nose and Throat: by D. Braden Kyle, M.D., 545—Insects: by D. Sharp, F.R.S., edited by S. F. Harmer, F.R.S., and A. E. Shipley, M.A., 545—The Story of Life's Mechanism: by H. W. Conn, 546—The Principles of Treatment and their Applications in Practical Medicine: by J. Mitchell Bruce, M.A. Aberd., M.D., F.R.C.P. Lond., 623—Text-book on Palæontology: by Karl von Zittel, translated by C. R. Eastman, Ph.D., 624—Health Abroad: A Medical Handbook of Travel: edited by Edmund Hobhouse, M.D. Oxon., 625—Professions for Boys and How to Enter Them: by M. L. Pechell and James J. Nolan; second edition, 625—Jahresbericht über die Fortschritte auf dem Gebiete der Chirurgie: redigirt und herausgegeben von Professor Dr. Hildebrand, 626—The Mechanics of Surgery: by Charles Truax, 626—Cancer, Illustrated by 1000 Cases from the Registers of the Middlesex Hospital and by 50 Selected Cases of Cancer of the Breast, &c.: by Thomas Wm. Nunn, F.R.C.S. Eng., 626—A Manual of Pharmaceutical Testing: by Barnard S. Proctor, F.I.C.; second edition, 625—A Laboratory Manual of Physiological Chemistry: by Elbert W. Rockwood, B.S., M.D., 626—Architectural Hygiene: by Banister F. Fletcher and H. Phillips Fletcher, 626—Essentials of Modern Treatment of Disease: for the Use of Practitioners: by K. M. Nadkarni, 710—Microscopic Researches on Glycogen: by Charles Creighton, M.D. Aberd, 711—La Pratique des Accouchements: Obstétrique Journalière: by Professor Henri Varnier, 711—Spencer's Disease: Dermatitis Multiformis Exfoliativa: by Walter Spencer, M.D. Brux, 712—A Manual of Diseases of the Nose and Throat: by C. Godfrey Coakley, A.M., M.D., 712—Natural and Artificial Methods of Ventilation, 712—A Text-book of the Practice of Medicine: by James M. Anders, M.D.; third edition, 782 — Geburtshilfliches Taschenphantom: by Dr. Arthur Mueller, 782—Who's Who at the War? 782—The Mirage of Two Buried Cities: by John Fletcher Horne, M.D. St. And., F.R.S. Edin., 782—A Text-book of Physiology: by Winfield S. Hall, Ph.D., M.D. Leipsic, 860—Clinical Studies in Vice and Insanity: by George R. Wilson, M.D. Edin., 861—Physiologie: a Manual for Students and Practitioners: by Howard D. Collins, M.D., and W. H. Rockwell, jun., M.D.; edited by Bern B. Gallaudet, M.D., 861—Darwin and Darwinism, Pure and Mixed: by P. Y. Alexander, M.A., LL.D., 944—An Elementary Course of Practical Zoology: by the late T. Jeffery Parker, D.Sc., F.R.S., and W. N. Parker, Ph.D., 945—The Flowering Plant: by J. R. Ainsworth Davis, M.A., F.C.P.; Third Edition, 945—The Excretion of Urea by the Skin in Health: by C. C. Easterbrook, M.A., M.B. Edin., 945—Unwritten Laws and Ideals: edited by E. H. Pitcairn, 946—The Literary Year-book, 1900, 946—Report of the Malaria Expedition of the Liverpool School of Tropical Medicine and Medical Parasitology; Memoir II.: by Major Ronald Ross, I.M.S., Dr. H. E. Annett, and Mr. E. E. Austen; with Supplementary Reports by Major G. M. Giles, I.M.S., and Dr. R. Fielding-Ould, 1010—Difficult Digestion due to Displacements: by A. Symons Eccles, M.B. Aberd., 1011—On Granular Kidney and Physiological Albuminuria; being the Lettsomian Lectures delivered before the Medical Society of London: by Samuel West, M.A., M.D. Oxon., F.R.C.P. Lond., 1011—Dictionary of National Biography: edited by Sidney Lee, 1012, 1519 — Medical Indoor Gymnastics; by D. G. M. Schreiber, M.D., 1013 — The Private Nurse; by Jessie Holmes M.R.B.N.A., 1014—The Health Resorts of Europe: by Thomas Linn, M.D., 1014—Home Nursing of Sick Children: by J. D. E. Mortimer, M.B., 1014—Bubonic Plague: its Course and Symptoms and Means of Prevention and Treatment: by Dr. José Verdes Montenegro; translated by W. Munro, M.D. Edin., 1076 — Le Système Nerveux Central: par Jules Soury, 1076—Life and Happiness: by Auguste Marrot, 1076—A Plea for a Simple Life and Fads of an Old Physician: by G. S. Keith, M.D., F.R.C.P. Edin., 1077—The Nursing Profession: How and Where to Train: by Sir Henry Burdett, K.C.B., 1077—Twentieth Century Practice: an International Encyclopædia of Modern Medical Science: edited by Thomas L. Stedman, M.D., 1136, 1807—Clinical Medicine: A Manual for the Use of Students and Junior Practitioners: by Judson S. Bury, M.D., F.R.C.P. Lond.; second edition, 1137—Surgical Anatomy: a Treatise on Human Anatomy in its Application to the Practice of Medicine and Surgery: by John B. Deaver, M.D., 1138—The Practice of Medicine: by the late M. Charteris, M.D.; eighth edition: edited by F. J. Charteris, M.B., Ch.B. Glasg., 1136—A Manual of Surgical Treatment: by W. Watson Cheyne, M.B. Edin., F.R.C.S. Eng., F.R.S., and F. F. Burghard, M.D., M.S. Lond., F.R.C.S. Eng.; second edition, 1138—Brain and Body, the Nervous System in Social Life: by Andrew Wilson, 1139—The Art of Feeding the Invalid, 1139—Bailey's Index to the *Times*, 1139—Practical Nursing: by Isla Stewart and Herbert E. Cuff, M.D. Lond., F.R.C.S. Eng., 1139—A Text-book of Physiology: by M. Foster, M.A., M.D. Lond., F.R.S., assisted by W. H. R. Rivers, M.A., M.D. Lond.; sixth edition; part iv., The Senses, 1214—Lessons in Elementary Physiology: by Thomas H. Huxley, LL.D., F.R.S., 1214—Lessons on Prescriptions and the Art of Prescribing: by W. Handsel Griffith, Ph.D., L.R.C.P.E., 1214—The Use of the Sphygmograph in Clinical Medicine: by Graham Steell, M.D. Edin., F.R.C.P. Lond., 1215—A Manual of Gynæcological Practice: by Dr. A. Dührssen; second English edition, translated and edited from the sixth German edition by John W. Taylor, F.R.C.S. Eng., and Frederick Edge, M.D. Lond., 1287—Outlines of the Comparative Physiology and Morphology of Animals: by Joseph le Conte, 1288—Outlines of Bacteriology: by Dr. L. H. Thoinot and E. J. Masselin; translated and adapted for English use with additions by W. St. Clair Symmers, M.B. Aberd., 1288—Diphtheria: by William R. Smith, M.D., D.Sc., F.R.S. Edin, 1288—Handbook of Physiology: by W. D. Halliburton, M.D. Lond., F.R.S.; sixteenth edition, 1289 — Electrophysiology: by Dr. W. Biedermann of Jena; translated by Frances A. Welby, 1366—The Treatment of Pelvic Inflammation through the Vagina: by William R. Pryor, M.D., 1367—A First Book in Organic Evolution: by D. Kerfoot Shute, A.B., M.D., 1368—Midwifery Notes for the Use of Students: by T. A. Glover, M.D. Edin., 1368—Burdett's Official Nursing Directory for 1900, 1369—Home Nursing: by Eveleen Harrison, 1369 — The Medical Annual and Practitioner's Index: a Work of Reference for Medical Practitioners, 1369 — The Grammar of Science: by Karl Pearson, M.A., F.R.S., second edition, 1447—A Manual of Zoology: by the late T. Jeffery Parker, D.Sc., F.R.S., and Wm. A. Haswell, M.A., D.Sc., F.R.S., 1448—Leçons de Clinique Médicale: par M. le Dr. Vires, 1448—A Book of Whales: by F. E. Beddard, M.A., F.R.S., 1449—Aids to Pharmacy: by A. Campbell Stark, 1449—The Experiment of Dr. Nevill: by Emeric Hulme Beaman, 1449—Diseases of Children: a Manual for Students and Practitioners: by G. M. Tuttle, M.D.; edited by Bern B. Gallaudet, M.D., 1520—Practice of Medicine: a Manual for Students and Practitioners: by G. E. Malsbury, M.D.; edited by Bern B. Gallaudet, M.D., 1521—L'Année Chirurgicale: Revue Encyclopédique de Chirurgie Générale et Spéciale; publiée par le Docteur A. Depage, 1521—The Student's Handbook of the Practice of Medicine: by H. Aubrey Husband, M.B., C.M. Edin., fifth edition, 1521—Acromegaly: by Dr. Maximilian Sternberg; translated by F. R. B. Atkinson, M.D., C.M. Edin., 1592 — On Neuroma and Neuro-fibromatosis: by Alexis Thomson, F.R.C.S. Edin., 1593—Rhinoplastic Operations, with a Description of Recent Improvements in the Indian Method: by D. F. Keegan, M.D. T.C.D., F.R.C.S. Eng., 1594—Archives of Neurology and Psychopathology, vol. ii., 1661—Anæsthetics, their Uses and Administration: by Dudley W. Buxton, M.D., B.S. Lond.; third edition, 1661—The Nervous System of the Child, its Growth and Health in Education: by Francis Warner, M.D., F.R.C.P. Lond., 1662—The Norwegian North Polar Expedition, 1893-1896, Scientific Results: edited by Fridtjof Nansen, vol. i., 1662—Golden Rules of Ophthalmic Practice: by Gustavus Hartridge, F.R.C.S. Eng., 1662—Manual of Chemistry, Inorganic and Organic, with an Introduction to the Study of Chemistry: by Arthur P. Luff, M.D., F.R.C.P., B.Sc. Lond., F.I.C., and Frederic James M. Page, B.Sc. Lond., F.I.C., A.R.S.M., 1662—The Absent-minded Beggar: by Rudyard Kipling, 1663—Mona Maclean: by Graham Travers (Margaret G. Todd, M.D. Brux.), fifteenth edition, 1663—Paris: Guides Conty Series; English edition, 1663—Heart Disease, with Special Reference to Prognosis and Treatment: by Sir William H. Broadbent, Bart., M.D., F.R.S., F.R.C.P. Lond., &c., and John F. H. Broadbent, M.A., M.D.Oxon., M.R.C.P. Lond., third edition, 1731—The Principles and Practice of Modern House Construction: edited by G. Lister Sutcliffe, 1732—Practical Gynæcology: a Handbook of the Diseases of Women: by Heywood Smith, M.A., M.D.Oxon., second edition, 1733—Ulcer of the Stomach and Duodenum and its Consequences: by Samuel Fenwick, M.D. St. And., F.R.C.P. Lond., and W. Soltau Fenwick, M.D., M.R.C.P. Lond., 1806—Atlas und Grundriss der Lehre vom Geburtsakt und der Operativen Geburtshilfe: by Dr. Oscar Schaeffer, fifth edition, 1807—A Manual of Medicine: edited by W. H. Allchin, M.D., F.R.C.P. Lond., F.R.S. Edin., 1887—The Diseases of Women: a Handbook for Students and Practitioners: by J. Bland-Sutton, F.R.C.S. Eng., and Arthur E. Giles, M.D., B.Sc. Lond., F.R.C.S. Edin.; second edition, 1887—A Treatise on Nasal Suppuration; or, Suppurative Diseases of the Nose and its Accessory Sinuses: by Dr. Ludwig Grünwald; translated from the Second German edition by William Lamb, M.D., M.C. Edin., M.R.C.P. Lond., 1888—Burdett's Hospitals and Charities, 1900: by Sir Henry Burdett, K.C.B., 1888—My Diocese during the War: by the Bishop of Natal, 1888—Records from General Practice: by J. Kingston Barton, M.R.C.P. Lond., M.R.C.S. Eng., 1889

PERIODICALS.—Janus, 34—Revue de Gynécologie et Chirurgie Abdominale, 35, 1594—Annales de Gynecologie et d'Obstétrique, 35, 1663—Archiv für Dermatologie und Syphilis, 171—The Journal of Anatomy and Physiology, 241, 1289—Revue d'Hygiène et de Police Sanitaire, 242—The Journal of State Medicine, 242—Journal of Physiology, 547, 1369—Quarterly Journal of Microscopical Science, 547, 1370—Veterinarian, 861, 1077, 1523—Veterinary Journal, 861, 1521—Treatment, 1077—Caledonian Medical Journal, 1139—Mercy and Truth, 1139, 1889—Edinburgh Medical Journal, 1215, 1889—Scottish Medical and Surgical Journal, 1215, 1889—Dublin Journal of Medical Science, 1215, 1889—The Medical Examiner, 1370—The Journal of the Sanitary Institute, 1370

Reynolds, Prof. E., gas-lighting, 969, 974
Rheumatic arthritis in a child, 457; diseases of the heart, treatment of, 923; endocarditis, the prevention of, 1169; fever, the heart wall in, 1352; fever and its complications, statistics of, 1581
Rheumatism, liq. auri brom-arsenatis in, 72; with embolism, 457; treatment of, 721, 761, 778, 871, 920, 933, 1016, 1094; acute, valvular disease in, the prevention of, 776; the organism (?) of, 964; acute, hyperpyrexia in, 1725
Rheumatoid arthritis, the excretion of nitrogen in, 706
Rhinoplastic Operations, with a Description of Recent Improvements in the Indian Method (review), 1594
Rhodes, Dr. J. M., insanity, 951
Rhodesia, the climate of, 1365
Ribs, fragility of, in anæmia, 239; in insanity, 347
Ribs, incomplete development of, 1437
Rice, Dr. W. R., public medical service, Coventry, 1542
Rice, Mr. J. D., femoral fractures, 1130
Richards, Dr. M., annual report for Chesterfield, 1027
Richardson, Dr. W. P., gangrene of the feet, 388
Richardson, Mr. S. W. F., the Boer wounded, 487
Richet, Dr. Ch., epilepsy, 554
Rickets, late, case of, 1071
Rideal, Dr. S., preservatives in food, 228
Risely, Dr. S., abscess of the brain, 388
Ritchie, Dr. James (Oxford), Bacteriology (review), 34
Ritchie, Dr. James (Edinburgh), pregnancy with complications, 169
River Plate, public health on the, 737
Rivers, Dr. W. H. R., Physiology (review), 1214
Roberts, Dr. F. T., an appeal, 48, 62; Neale's Digest, 420
Roberts, Mr. E., optic neuritis, 1350
Roberts, Mr. H., homes for incurables, 1925
Roberts, Dr. Ll., specimen exhibited, 315
Roberts and Co., Messrs., Trousseau's wine, 898
Robertson, Dr. J. G., aneurysm, 1443
Robertson, Dr. R., the late, 65
Robertson, Dr. W. G. A., saliva, 808, 1363
Robinson, Dr. M. K., boric acid in food, 131
Robinson, Mr. T., measles, 941
Robson, Mr. A. M., the stomach, 671, 747, 830, 947
Roche, Prof. A., Irish schools, 689
Rockwell, Dr. W. H., Physiology (review), 861
Rockwood, Dr. E. W., Physiological Chemistry (review), 626
Rod or prison for juvenile offenders? 248
Roe, Mr. C. D., sanatoria, 590

ROENTGEN RAYS.—The rays in favus (Dr. Norman Walker), 27—The rays in lupus (Dr. Norman Walker), 27; (Mr. J. F. Hall-Edwards), 637—Ray apparatus at a missionary station, 72—Packing-needle in the descending colon localised by the rays (Mr. N. Davies-Colley), 96—Fractured patella discovered by means of the rays (Mr. A. Barker), 169—Depilation by the rays (Dr. N. Wood), 231—Roentgen Rays in Medical Work (Dr. D. Walsh) (review), 317—Congress of Medical Electrology and Radiology in Paris, 398, 1807—Foreign body in the eye shown by the rays (Mr. C. G. Lee), 460—Focus-tube dermatitis (Dr. A. H. Hobbs), 465—Renal calculi shown by the rays (Mr. Wuest), 503—Radiographic researches on the topographical relations of the brain, &c. (Dr. Paul Regnier and Dr. Jules Glover), 525—Skiagram of hallux varus (Mr. J. Poland), 621—Radiographs of fractures (Mr. Noble Smith), 622—Superfluous hair destroyed by the rays (Mr. James Startin), 654—The rays in dental cases (Mr. G. J. Goldie), 939—Dislocation of the epiphysis of a metacarpal bone shown by the rays (Mr. E. K. Herring), 1130—Demonstration on the rays (Mr. J. H. Gardiner, F.C.S., and Mr. James Wimshurst, F.R.S.), 1212—The rays in the diagnosis of diseases of the nose and throat (Dr. John Macintyre), 1591

Rolleston, Dr. H. D., hæmo-pneumothorax, 458

ROME, CORRESPONDENCE FROM.—Hygiene and the Holy Year, 68—Dr. Mazzoni and the ceremony of the Porta Santa, 68—The crusade against malaria, 69—Plague at San Paulo, 69—A contre-coup to the Holy Year, 136—Three medical worthies, 137—Death of Prof. Francesco Orsi, 204—The Vatican consultants in medicine and surgery, 205—Award of the Bressa prize, 205—Influenza, 274, 349, 426—La Villa Igiea, Palermo, 275—A congress of international hygiene, 349—Influenza and the Holy Year, 426—Small-pox, 503—Italy and the wounded from South Africa, 503—Sanitary precautions at the French frontier, 503—Illness of Dr. Baccelli, 503—Apparent death and premature burial, 582, 661—The English-speaking practitioner in Italy, 582—The crusade against tuberculosis, 661—Post nubila Phœbus, 737—Public health on the River Plate, 737—THE LANCET and Italy's climatic resources, 809—The Senator Lorenzo Bruno, 810—How the "Rè galantuomo" died, 810—International hygiene: the lazzaretto of Mogador, 889—In memory of Italy's surgeons fallen in battle, 889—Prof. Robert Koch in Italy, 889—Italian hygiene at the Paris Exhibition, 1036—Cacodylate of soda, 1037—Pro montibus, 1173—Oysters and infective diseases, 1173—The international congress against tuberculosis, 1329—Reciprocity of medical practice, 1913—Award of the Balbi-Valier prize, 1914—Medical legislators, 1914—The malaria problem, 1914

Rose, Prof. W., Manual of Surgery (review), 391
Rosenheim, Mr. Otto, uric acid, 1708
Ross, Dr. D., gout, 1133
Ross, Maj. R., Malaria Expedition, &c. (review), 1010; a suggestion, 1400
Rotunda Hospital (see Dublin)
Roughton, Mr. E. W., dislocation of the hips, 102; injury to femur, 233; nasal discharges, 1073
Row, Dr. R., atropine in plague, 1445
Rowan, Dr. J., sarcoma, 1135
Rowland, Mr. S., liquid air, 1130; serum diagnosis, 1441
Royal Academy of Arts, 1312
Royal Army Medical Corps: pay in India, 64; in Egypt, 333; pass list, 495; nominations, 579; enlistment, 664; *Blackwood's Magazine*, 803; officers who have lost their lives or been wounded in the war, 804, 964, 1026, 1029, 1755, 1830; officers mentioned in despatches, 882, 1029; messes in India, 882; Parliamentary references, 740, 894, 948, 1039; the stall at the National Bazaar, 1465, 1601; strength in South Africa, 1819
Royal Army Medical Corps (see also Services, War)
Royal Army Medical Corps Fund, 261, 334, 393, 416, 477, 572, 888, 1029, 1143, 1222, 1817

Map showing (1) the Administrative County of London, (2) the Area of the Metropolitan Water-supply, and (3) the Metropolitan and City Police Area, accompanying article headed "The Royal Commission on the Metropolitan Water-supply," 330

Portrait of the late Sir Thomas Grainger Stewart, 413

Illustration showing a Field of a Transverse Section of the Liver closely underlying a Hepatic Mucoid Cyst (Mr. W. C. McDonnell), 453

Various Photoprints and Drawings illustrating lectures on the Anatomy and Pathology of the Rarer Forms of Hernia (Mr. B. G. A. Moynihan), 513, 514, 516, 518, 519, 520, 597, 598

Ten Photoprints of Views and Sections of the Kidney and one of the Ureter, accompanying paper on Tuberculous Disease of the Kidney, its Etiology, Pathology, and Surgical Treatment (Dr. D. Newman), 528, 529, 530, 531, 602, 603, 700

Eight Pulse Tracings described in paper on Pulsus Paradoxus (Dr. J. Hay), 536

Various Diagrams illustrating paper on the Relation of Blood Vessels to Lymphatic Vessels (Dr. C. H. Leaf), 606, 607

Two Photoprints of Large Renal Calculus described in paper on the Surgery of the Kidney (Mr. L. W. Bickle), 609

Two Drawings of Metatarsal Bones, Two Drawings of a Foot, and Photoprint of Casts of a Foot before and after Operation, accompanying paper on Hallux Valgus and Hallux Varus (Mr. J. J. Clarke), 609, 611

Drawing of Uterus containing Fœtus from a case of Pregnancy Complicated by Fibrous Tumour of the Supra- and Infra-vaginal Cervix (Dr. W. Duncan), 614

Two Drawings of Instruments used in an Improved Method of Eye Measurement (Mr. K. Scott), 627

Improved Ear-Drums (Mr. H. Dadysett), 628

Antiseptic Muzzle (Lord F. B. Bruce and Surg.-Capt. E. Kingscote), 628

Illustrations accompanying Mr. A. Mayo Robson's lectures on the Surgery of the Stomach:—Diagram of the Abdomen divided into Four Regions; Seven Sketches of the Stomach showing respectively Kink of the Pylorus from Adhesions, Hour-glass Contraction, Bifid and Trifid Stomach, and Pyloroplasty over a Bone Bobbin; Six Sketches showing Different Methods of Gastroplication; Outline Diagram of Patient showing the Position of Incisions; Two Sketches showing the Attachment of the Stomach to the Skin, 672, 750, 753, 756, 831, 839, 840

Three Half-length Portraits of Patients, One Front View of Face, and Diagram of Brachial Plexus, illustrating description of a case of Rupture of the Brachial Plexus (Dr. P. Stewart and Mr. M. Collier), 692, 693

Diagram of the Ribs, Sternum, and Clavicles and Reproduction of a Photograph from a Dead Body on which the Operation was performed, to illustrate a Suggestion for a Method of Opening the Pericardial Sac (Dr. C. Ogle and Mr. H. Allingham), 694, 695

Drawings of Attic Curette and Ossicles of the Ear, accompanying paper on Complete Ossiculectomy (Mr. R. Lake), 703

Illustrations accompanying Dr. P. Horton-Smith's lectures on the Typhoid Bacillus and Typhoid Fever:—Five Microscope Fields, showing Three Varieties of Bacillus Coli, Gärtner's Bacillus Enteritidis, and Bacillus Typhosus; Three Microscope Fields showing various Bacteria in the Urine ("Bacteriuria"); Two Microscope Fields showing Agglutination of the Typhoid Bacillus and also of Gärtner's Bacillus; Six Agglutination Curves; Four Test-tubes containing Cultures; Two Microscope Fields containing Urine; Two Test-tubes containing Urine, 823, 918, 919, 1052, 1054, 1056, 1060, 1061

Illustrations accompanying Sir William Banks's lectures on Cancer of the Breast:—Whole Page containing Six Photoprints of sections showing Chronic Mastitis; Photoprint showing the "complete" as opposed to the "redundant" operation; Whole Page containing Six Photoprints showing parasites (1) in a Mammary Carcinoma; (2) in an Axillary Gland; and (3) in the Lung of an Inoculated Guinea-pig, 848, 995, 997

Head-rest on a Barber's Chair, 862

Illustrations accompanying Dr. Cheadle's lectures on Some Cirrhoses of the Liver:—Portions of Four Microscope Fields showing Hypertrophic and Syphilitic Cirrhosis of the Liver; Portions of Two Microscope Fields showing extreme Degeneration of the Heart Wall and Granular Changes in Muscle Fibres from the Left Ventricle in Alcoholic Cirrhosis of the Liver; Portions of Two Microscopic Fields showing Cardiac Cirrhosis, 904, 907, 908, 909, 985, 986, 1049

Parasitic Crustacean as a Foreign Body on the Cornea (Dr. R. D. Batten), 1002

The "Lupa Humaniser," 1077

Three Drawings of Myomatous Uteri, described in lecture on the Modern Treatment of Uterine Fibroids (Dr. W. Duncan), 1110, 1111, 1114

Seven Diagrams of the Head of the Humerus, Portrait of Patient (face only), and two Views of Patient's Lower Limbs, accompanying paper on Coxa Vara (Mr. C. B. Keetley), 1115, 1117, 1118

Skiagram showing Dislocation of the Epiphysis of a Metacarpal Bone (Mr. E. K. Herring), 1131

Apparatus for the Local Application of Ethyl Chloride, 1139

LIST OF ILLUSTRATIONS—(*Continued*).

Portrait of the late Sir William O. Priestley, 1149

Two Drawings of an Œsophagoscope, Three Drawings of a Rod for Exploring the Stomach, Photoprint of Stomach filled with Plaster-of-Paris, Three Photoprints of Models of the Stomach, Three Views of a Gastroscope, Two Photoprints showing the Methods of introducing the Gastroscope and inspecting the Stomach, described in paper on Endoscopy of the Œsophagus and Stomach (Dr. Georg Kelling), 1190, 1192, 1193, 1194, 1196, 1197

The "Allenburys" Milk Pasteuriser, 1215

Whole Page containing Six Photographs of Gelatin Plates to illustrate THE LANCET Special Commission on Glycerinated Calf Vaccine Lymphs, 1236

Representations of Nerve Cells, accompanying lecture on the Effect of Alcohol on the Human Brain (Mr. V. Horsley), 1272, 1273

Chart showing Plague Mortality in India, explained in Observations on the Epidemiology of Plague (Mr. T. F. Pearse), 1274

Two Views of Back of Patient and Diagrams of Pelvis, accompanying description of a case of Kyphotic Pelvis (Dr. J. B. Hellier), 1280, 1281

New Tonsil Forceps (Dr. H. Tilley), 1291

Two Views of an Air Filter, accompanying description of the Warming and Lighting of the London Hippodrome, 1316

Four Outline Diagrams of Patients, accompanying lecture on Ptosis of the Liver and the "Floating Lobe" (Mr. F. Treves), 1341, 1342

Portions of Two Microscope Fields showing Cardiac Muscle Fibres, accompanying paper on the Heart-wall in Diphtheria, Rheumatic Fever, and Chorea (Dr. F. J. Poynton), 1352, 1353

Two Diagrams accompanying description of a case of Combined External and Internal Strangulation (Mr. A. Carless), 1357

Iodised Phenol Antiseptic Hydrocele Outfit (Mr. F. Deane), 1370

Photoprint of the Interior of the Left Ventricle of the Heart, accompanying description of a Chronic Abscess of the Pericardium (Dr. D. Hunter), 1435

Half-length Portrait of Patient showing want of Symmetry owing to the Incomplete Development of the Third and Fourth Right Ribs (Mr. F. B. Jefferies), 1437

Invalid Bedstead with Lifting Arrangement, 1450

Twelve Outline Diagrams of Patients showing Bullet Wounds, accompanying address on the Wounded in the Present War (Sir William Mac Cormac), 1487

Five Photoprints and Two Diagrams of Fractures, accompanying lecture on the Operative Treatment of Simple Fractures (Mr. W. A. Lane), 1490, 1491, 1492

Photoprint of Section of a Retro-peritoneal Fibro-cystic Tumour, showing Muscle Cells (Mr. D. Douglas-Crawford), 1514

New Form of Vaginal Douche Tube (Mr. A. Duke), 1522

Seven Photoprints showing Massage in Recent Fracture of the Leg, as described in a lecture on the Use of Massage in Recent Fractures and other Common Injuries (Mr. W. H. Bennett), 1570, 1571, 1572, 1573

Two Temperature Charts accompanying paper on Preventive Inoculation against Typhoid Fever (Mr. A. G. R. Foulerton), 1580

Three Views of a Calculus which passed through the Ureter and Urethra (Maj. J. A. Cunningham), 1586

Photoprint of Indiarubber and String attached, removed from the Ear (Mr. J. G. Macaskie), 1586

Boer Trenches, 1609

Diagram of Plastic Operation for the Closure of an Ulcer at the Umbilicus (Dr. J. Pinkerton), 1657

Tonsil Clamp (Dr. D. W. Aitken), 1664

Pocket Spittoon, 1664

Onah Vaginal Douche, 1664

"Portia" Combined Stocking Suspender and Shoulder Support, 1664

Two Views of Body and Thighs of Patient suffering from Bilateral Dislocation of the Hip, presumably congenital (Dr. T. P. Cowen), 1717

Diagram representing the Relative Position of Clots in the Brain, referred to in paper on Cases of Brain Injury Clinically Examined (Mr. E. E. Dwyer), 1720

Two Diagrams of the Sigmoid Flexure, accompanying paper on the Surgical Aspects of Constipation (Mr. S. L. Woolmer), 1721

Diagram showing the Position of the Parts in a case of Strangulated Femoral Hernia in which Gangrene was precipitated by an Intra-abdominal Volvulus (Mr. R. L. Knaggs), 1727

New Clinical Laboratories of the Westminster Hospital, 1748

Five Diagrams of Brain, Reflex Arc, and Neurones, Three Drawings to show Degeneration of Nerves, Two Transverse Sections of the Sciatic Nerve, and Transverse Section of the Spinal Cord, Microscope Field, showing Hypoglossal Nuclei, Double Whole Page containing Seventeen Histological Micro-Photographs, accompanying lecture on the Degeneration of the Neurone (Dr. F. W. Mott), 1781, 1782, 1783, 1784, 1785, 1786, 1787, 1849, 1855

Aseptic Vaccination Case (Mr. C. Corben), 1808

Portable Spittoon, 1808

Plan and Interior of the New Operating Theatre at the Radcliffe Infirmary and Plans of the Ground Floor and Upper Floor of the new Pathological Laboratories, Oxford, 1822, 1823, 1824

Full-length Portraits (1) of "General and Mrs. Tom Thumb" (dwarfs), (2) of Winkelmeyer (a giant), and (3) of a case of Degenerative Hypoplasia of the Skeleton, Photoprints of Bones affected with Degenerative Hyperplasia, described in paper on Primary Disorders of Growth (Mr. H. Gilford), 1868, 1869, 1870, 1872

Photoprint of Lower Legs, accompanying description of a case of Syphilitic Fibro-spongioid Osteitis (Mr. J. B. Hall), 1875

Chart showing Excretion of Urine and Urea, accompanying paper on the Excretion of Urinary Water and Urea (Dr. J. B. Nash), 1878

Diagram illustrating Removal of a Gall-stone from the Common Bile Duct by the Duodenal Incision (Mr. F. Page), 1885

ABSTRACT OF

A Clinical Lecture

ON

CANCER OF THE PENIS.

Delivered at St. George's Hospital on Nov. 12th, 1899,

BY A. MARMADUKE SHEILD, M.B. CANTAB., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE HOSPITAL AND LECTURER ON PRACTICAL SURGERY.

GENTLEMEN,—You are aware that I lay great stress upon the importance of your perfecting yourselves in the knowledge of common maladies, or of such diseases as are of great importance in daily practice. The distressing complaint which we are about to consider to-day falls into the latter category. It can hardly be called common. Probably it does not amount to more than one or two per cent. of all cancers. Yet instances of the malady may "crop up" at any time in your future practice, and if you mismanage the complaint, if you fail to grasp the full significance of the symptoms in their early stage, you may do a patient grave damage or allow the period to pass when surgical intervention can alone be of avail. Some weeks ago, you may remember, a man came to show himself upon whom I had operated some four years ago. He still, I am glad to say, remains well, and I thought the case so important that I take this opportunity of bringing the subject before you to-day in a practical light.

As local irritation is the great exciter or producer of epithelioma upon muco-cutaneous structures, we find, what might *a priori* be expected, that the majority of the victims of cancer of the penis have been life-long sufferers from phimosis. They have never been able to retract the foreskin, secretion and dirt have accumulated beneath, and thus the affection has originated. I have looked through long lists of cases, but only in a few instances have I found the disease to originate in men who have an uncovered glans penis and a retracted foreskin. The rarity of this complaint in Jews is traditional. This grave consideration is a powerful incentive for urging circumcision upon children with elongated foreskins. It is still more a powerful consideration in the case of adults who begin to get "soreness" or irritation beneath a phimosed prepuce; such cases are commonly enough dubbed "gouty eczema." I believe this to be a misnomer. Timely operation and removal of the source of irritation may doubtless ward off one of the most distressing diseases that a human being can suffer from. There can hardly be a more important matter for the care and consideration of the family practitioner than that, and I implore you to lay it closely to heart.

As you may naturally expect, epithelioma of the penis is an affection of advanced life, yet there are striking exceptions to this rule. I myself have seen two cases in which the patients were under the age of 35 years, and a case is recorded where the victim was only 22 years of age.[1] Indeed, it is curious at how early an age cancer may occasionally be found to attack the rectum or the genitals of either sex. I have known grave diagnostic errors committed from want of knowledge of this fact. I must strongly draw your attention to it. Mistakes are made by supposing that cancerous diseases follow fixed laws, and diagnostic confusion with syphilis is especially likely to occur in young men, as I shall presently point out. I do not know that soot has much influence in causing cancer of the penis. The cancer of chimney-sweeps is essentially an integumentary disease mostly affecting the scrotum. In exceptional, very exceptional, cases cancer may attack a non-phimosed penis; I know of such cases in literature, but I have only seen one. Here the cancer sprouted from the scar of an imperfectly healed chronic syphilitic ulcer. A case is also related where the disease originated in injury, but I have never witnessed such an occurrence. The statement that these cases are due to contact infection—namely, that the wife of the patient is suffering from a cancerous cervix—has little true value. One authority stated in what he terms the "heat of a clinical lecture" that such cases were common, but on requesting him to furnish one example he was unable to do so.[2] I know of only one reputed case and this was probably coincidence. The disease in its early beginnings may be a superficial erosion, a warty growth, or a nodular mass. If the prepuce cannot be retracted some discharge commonly issues from the orifice. This may be hæmorrhagic or sero-purulent. Attacks of redness, pain, and swelling occasionally occur. The discharge is peculiarly fœtid as soon as ulceration begins. At last a hard lump like a haricot bean is felt beneath the prepuce and the disease is established. In other instances perhaps the prepuce can be retracted and the growth will be seen commencing as a small nodule or a vegetating wart which "itches and burns." The latter symptom is of fearful import in such cases. Too often—far too often—this little lesion is treated with caustics, as nitric acid or nitrate of silver, and thus the disease is not arrested, but is stimulated into serious and progressive growth. Infiltration of the tissues takes place at the base of the wart and ultimately a foul ulcer forms, surrounded with hard gristly edges and covered with fungous protuberant granulations exuding a most offensive discharge. Still later the body of the organ becomes infiltrated with disease, as is evidenced by its hard feeling and increased size. The corpora cavernosa are especially affected, the urethra remaining free, comparatively speaking. The condition of the inguinal and lumbar glands is of vast importance in this malady. Sooner or later the lumbar glands become affected and agonising "crampy" neuralgic pains with œdema of the legs supervene. Sometimes a foul and extensive ulcer forms in one or both groins and the patient may be carried off by hæmorrhage from the femoral vessels. I recollect a case in the Hunter Ward which happened when I was a student in which death occurred in this way. More commonly, however, the patient sinks from exhaustion and sepsis produced by the fungating sores and by "secondary" growths in the lumbar and inguinal glands. Indeed, these cases are among the most terrible that we meet with, and did patients only realise the full horrors of neglected malignant disease of these parts they would not be so difficult to persuade of the necessity for early or preventive treatment. Secondary growths in the lungs or other viscera are exceedingly rare though not unknown. The period of life in a case not submitted to operation is variously estimated. I advise you not to prophesy concerning matters beyond your ken. Cancer, above all other maladies, runs very different courses in different individuals and confident prophecies are apt to be rudely falsified. A very difficult but fortunately rare complication of advanced penile cancer is retention of urine. Probably in such cases the disease commences in the urethra. An instance of this occurred in the practice of the late Mr. Henry Smith.[3] Here the surgeon seemed to have relieved the retention by forcing a silver instrument through the growth. In these days, supposing the patient declined the radical operation of amputation, paracentesis of the bladder or opening the urethra behind the growth would be advisable. It is an awkward complication of such cases and you may possibly meet with it in future practice.

Such being a sketch of the cause and terminations of these cases, we next turn to the diagnosis. It is upon this I wish especially to dwell, because it is here that disaster and much blame and after-reproach may fall upon the medical man who acts wrongly or injudiciously. The "pre-cancerous" or early stage is marked by so-called "chronic eczema" or the formation of a warty growth or nodule. When these conditions, however slight, are associated with phimosis and advancing life the case at once assumes a most anxious aspect. The right course here is at once to advise circumcision and apply local antiseptic and soothing remedies. Of these carbolic acid, boric acid, and mercurial preparations take the first place, but they must all be applied very dilute. The case must be carefully watched and once the diagnosis is made very free removal must be carried out. We will speak of this presently. I would only again caution you against complicating the diagnosis by the application of inefficient caustics. I do this from my own experience of what I have seen from thus treating early cancerous conditions in the tongue, lips, and elsewhere. I am aware that

[1] Transactions of the Pathological Society of London, vol. xi

[3] THE LANCET, Jan. 31st, 1863.

more than one authority advises a contrary course. With the greatest diffidence I must directly differ from them, and I have no hesitation in speaking strongly against the practice.

There are two very peculiar conditions associated with early cancer of the penis. The one is the formation of horns, the other the occurrence of malignant dermatitis (Paget's disease) of the integument of the glans. An epitheliomatous horn is always indurated at its base; it consists of massed epithelial material, frequently being "piled up" upon the summit of a wart. I show you here the remarkable specimen kindly sent to me by Dr. Walker of Peterborough who operated. The parts have somewhat shrivelled and the appearances do not give you much idea of what one saw clinically, for in this very striking case "Paget's disease" was evident behind and around the horny growths.

A case of this remarkable condition was shown by Mr. Pearce Gould at a meeting of the Pathological Society of London in February, 1887. The patient, aged 52 years, had as usual congenital phimosis, for which he was circumcised. The wound never soundly healed and a small wart developed. Upon this a horn grew, and it is stated that the patient regularly pared it down. After removal epitheliomatous structures were found at the base. Five cases of penile horns are stated in the same paper to have been collected by Erasmus Wilson, six by Lebert, and other authors. Horns may also be in exceptional cases non-epitheliomatous, as in a case related Dr. Van Orloff.[4] Here the patient was a boy, aged only 14 years, and the horn grew from a wart behind the prepuce. So, as a rarity, a horn may originate in an ulcerating sebaceous cyst. A specimen measuring one and three-eighths of an inch in circumference was removed by Brunton of Philadelphia.[5]

The practical lesson you learn from all this is obvious. A horny growth on the penis usually has an epitheliomatous base, and if this be the case free extirpation cannot be too early carried out. The condition is a rare one, ulceration and warty papillomatous structures being far more commonly met with. Should the horn originate from a sebaceous cyst induration at the base will be absent.

The so-called malignant dermatitis is quite unmistakeable in appearance. Usually occurring about the nipple in the female, it may exceptionally be found in other parts, and I myself have described a case occurring in an elderly man above the pubes. The patch of disease is of a vivid red, raw, glazed appearance, there is a viscid alkaline discharge, and whitish islets of epithelium are scattered about upon it. To these the name of "psoriasis" is often wrongly given. If you can lightly "pinch up" a portion of the affected patch between the finger and thumb a definite slight thickening may be felt. Now, this condition is certainly cancerous, and I know of no local remedies which will definitely arrest or cure it. Early free extirpation is the sole safe resource. It is in this condition especially that the remarkable "cell forms" termed psorosperms are so common, and the latest theories regarding the true nature of these and their relation to cancer may well be worthy of your attention.[6]

Tarnovsky of St. Petersburg describes a case of psorospermosis (Paget's disease) of the glans penis in a syphilitic patient. The patch resembled eczema and was accompanied by ulceration, itching, and pain. It is important to note that treatment for four months failed to make any impression upon the disease. Another case is related by Pospeloff of Moscow.[7] In Crocker's case the skin of the penis and scrotum were both affected by the disease.[8]

I have an idea that "Paget's disease" of the glans penis or prepuce is really more common than is generally described, and looking back on cases I have seen discussed as "intractable" or "gouty" eczema under the foreskin of elderly men I cannot help thinking that they were really of this nature. The vivid raw, red, glazed appearance is very striking and at once engages attention, if the observer be familiar with it from observation of previous cases. The whitish patches of epithelium may be very abundant and largely conceal the vivid red surface beneath. In some instances, as pointed out, cancer begins as a nodule on the glans penis, which breaks down and leaves an excavated ulcer. Indeed, I may say with truth that cancer of the penis assumes two distinct forms—the warty or papillary and the excavated ulcerating variety.

This brings me to speak of a very important subject in connexion with these cases—the condition of the inguinal and lumbar glands. The inguinal glands receive the lymph from the superficial area (skin and mucous membrane of the urethra) of the penis, while the lymph from the deeper parts of the organ passes to the lumbar glands along the dorsal vein of the penis. Consequently it is the inguinal glands which are most early affected in this disorder, the lumbar glands only becoming implicated in neglected cases, when the growth has extended along the corpora cavernosa. Now the greatest peculiarities are observed in the way the glands become affected. In some quite advanced cases the glands escape. In others they are early affected. The more chronic, warty, or horny the cancer the less likely are the glands to suffer. The more ulcerating, unequally extending, and exuberant the growth, the more early and hopeless will be glandular contamination. Thus enlarged glands in the groin must be taken with reserve in diagnosis. Moreover in an ulcerating cancer the glands may inflame and even suppurate, for not only "cancer"-cells but pyogenic organisms gain access to them. This is of great importance in the treatment. When the inguinal or lumbar glands are extremely infected anything like great prolongation of life is hardly to be looked for as a result of operation. It is, however, often justifiable to amputate in such cases, only to relieve the patient of the terrible local suffering caused by a mass of ulcerating cancer.

In the more advanced cases diagnosis is seldom difficult. The fœtor, the infiltration of growth, the warty granulations are all as typical of cancer as is the case elsewhere. Gummatous ulceration of the penis may simulate cancer, but here the base of the sore is devoid of gristle-like hardness, the margins are serpiginous, and other signs of syphilis will usually be present, as scars on the tongue and legs. Moreover, large doses of iodides soon effect obvious improvement. Should cancer engraft itself upon an old syphilitic sore the sprouting warty mass will soon make the true nature evident. This will be well seen in a case narrated at the end of this lecture. It is otherwise in the diagnosis between primary chancre and cancer. Here problems arise which must be investigated with the extremes of caution or very deplorable errors may arise. I do not like to mention names in connexion with these cases for fear of identification. I may tell you, however, that cases have occurred where amputation has been performed on the diagnosis of cancer when a roseolous rash and subsequent examination showed that the true malady was primary syphilis. I need only mention this terrible error to you to show you the difficulty that surrounds some of these cases and how warily you have to walk regarding them. Great diagnostic difficulties arise in regard to "relapsing" chancres. Some of you may know, or will hereafter learn, that chancres may develop *de novo* upon the site of former chancres, perhaps as long as 12 months after the original disease. I have had a case in my own practice where this occurred twice at intervals of 12 months, and the diagnosis of cancer might readily have been made. I will give you the following rules in dealing with such difficulties. Firstly, remember that it is within the boundaries of possibility that a man of any age, of any calling, may have a "hard" chancre beneath a phimosed prepuce. Secondly, cancer may occur in comparatively young men.

The ulcer should be inspected, if needful circumcision can first be performed. Should there be any doubt of its nature, and this is likely enough, full consultation should be sought. If still difficulties arise, mercury and iodides should be administered in full doses, and we must wait. It has happened to me more than once to be placed in these perplexities, and it is better to wait for a confirmatory "rash" than to operate recklessly. I may remark that the development of the sore is far more rapid in syphilis than in cancer, and the glands in the groin become more rapidly enlarged in chancre than in cancer. The microscopical test of excising a portion of the edge of the sore under cocaine must never be omitted. Unless the appearances are quite definite of epithelioma you had better distrust the evidence. It is my practice in such cases to send portions to two separate pathologists of acknowledged repute, and to consider their evidence in conjunction with clinical manifestations.

Next, I must draw your attention to the possible diagnostic difficulties which may arise between cancer and gummata of

[4] Brit. Med. Jour., August 13th, 1887.

the body of the organ, or that rare condition known as "gouty tumour" of the penis. Here you may especially note that cancer of the penis is in its commencement essentially a superficial disease. It begins on the surface and extends downwards. A hard nodule commencing in the corpora can hardly be carcinoma. Cancer commencing in the urethra is very rare, and usually associated with old sinuses or other causes of chronic irritation. Gummata of the body of the penis may be hard and are very threatening in aspect, so that the hasty diagnosis of cancer is readily made. The gouty tumour is of the same nature as Dupuytren's contraction of the palmar fascia. Indeed, I have once seen these two conditions associated in the same person. It is a localised fibrosis leading to thickening, and perhaps deformity, of the organ. The patient is usually elderly, and the signs of gout are marked. In these cases also the diagnosis of carcinoma has been arrived at. An allusion is made to the gouty infiltration of the penis in the *British Medical Journal* of May 8th, 1886. In the case referred to a distinguished Scotch surgeon wished to amputate the organ for supposed cancer. A typical case is related by Cameron of Glasgow.[9] Here the patient was a gentleman past middle life, and he had a tumour in the penis, oval and about the size of a horsebean. During erection the organ became distorted. The question here arose as to its being of a "malignant or scirrhous" nature. It is worthy of remark that the patient in this case had a little "knotty" thickening in the palmar fascia leading to contraction of the little finger. The concidence was very striking.

No doubt some such tumours are due to gout, others to gummatous deposit, and under large doses of iodide of potash very threatening-looking swellings may disappear which have developed slowly in the corpora cavernosa.

Sarcoma of the penis is very rare and probably you will never meet with an instance of it. I only mention it here for the sake of completeness. A case is related by Mr. Battle[10] well worthy of note. The patient was a retired clergyman, aged 60 years. He noticed a gradual enlargement of the end of the penis with a blood-stained discharge from under the prepuce. Hæmorrhage seems to have been a marked symptom. There is a specimen of melanotic disease in our museum removed by Mr. Holmes in 1872, and Mr. Golding-Bird is stated to have had another case at Guy's Hospital of spindle-celled sarcoma. The diagnosis of these cases prior to removal is uncertain, except in the case of melanosis, but the clinical characters of malignant disease are usually well marked.

Having thus spoken of the important diagnostic difficulties which may beset this subject the appropriate treatment must now engage our attention. Firstly, what course are we to pursue in the very early or dubious cases? Take the case of an elderly man with whitish thickening of the epithelium over the glans and the formation of an itching wart or horn with questionable induration at its base. I am sure in such cases that amputation of the end of the organ is the safer practice and that which would be followed by the best ultimate results. Few patients will submit to such radical treatment for an affection they consider but slight. If any other local treatment be adopted of a destructive nature it must be efficient. The action of such agents as nitric acid is very difficult to control and I strongly oppose them. Either free excision of the diseased part must be practised or it must be eradicated with the actual cautery. The resulting healing leaves a deformed organ and the scar is only too likely soon to show signs of fresh mischief, so the operation of amputation becomes absolutely needful and had better have been performed at first.

The instance of horny growth on the penis referred to affords a good example of the difficulties associated with treatment of early cancer. This very interesting and important case was sent to me by Dr. Walker of Peterborough for an opinion in 1897. It is principally of interest here as showing the treatment I advise in such conditions. The question was, should the horn and its diseased base be cut out or should amputation be performed? Seeing that "malignant dermatitis" was present over the glans, with vivid red patches and masses of thickened and fissured white epithelium, I felt sure that any partial operation would leave disease behind and I most strongly urged amputation of the anterior end of the organ. The greatest opposition was expressed to this course, but I remained inflexible and it was ultimately carried out. I heard lately that this patient died from bronchitis about a year or 14 months after the operation. He had good micturition power, and there was no sign of return. I may add that there was no reason to suspect implication of the inguinal glands.

In early cases, when the body of the penis is free, amputation must be performed about the centre of the organ. When, however, the surgeon is confronted with those common cases where the disease has been concealed and serious infiltration of the corpora cavernosa has occurred I am sure that removal of the whole organ after the method described by Gould is the best treatment. In such cases the question of removal of the testes also will arise. Here there is always room for difference of opinion. My own practice would be to leave the organs on account of the mental depression that must arise in adding such an operation to one already sufficiently distressing. The idea of division of the cord, to cause testicular atrophy, has been present in my mind, but hitherto I have not adopted it. Should the scrotum and testes be unhappily implicated the removal of such a loathsome condition may be justifiable. In bad cases, where the whole genital apparatus is involved, the penis and scrotum with the testes have been successfully removed, as in a case under the care of Mr. Vincent Jackson of Wolverhampton.[11] Here the surgeon met with rather free hæmorrhage in detaching the crura. This has also been my own experience.

I am not going to waste your time by describing the various operations for removal of the penis. If any one of you undertakes this proceeding he will probably carefully study the various methods and select the most appropriate. The remarks I shall make will be therefore rather general. Firstly, I may mention the use of the hot galvano-ecraseur wire only to condemn it. Secondly, the great difficulty of these operations lies in the management of the urethra. Gould's operation described in THE LANCET of May 20th, 1882 (p. 821), is infinitely to be preferred when the amputation has to be done close to the scrotum. Nothing is more miserable than the condition of a man whose urethra opens flush with the pubes. At every effort of micturition urine runs over the scrotum and thighs, which become eczematous and red, and no apparatus can be constructed to carry away the urine from the person. It is otherwise when the urethra projects from the perineum. In seclusion the patient micturites like the opposite sex and when out of doors he uses a receptacle. An excellent apparatus is one made out of glass and Mr. Hawksley has lately fitted a patient of mine with

Apparatus for a perineal urethral opening.

this contrivance with striking benefit. The patient applies the urinal when he wishes to micturite and the stream is carried away clear of the clothes by the tube. It should be a leading principle always to make a perineal opening in cases where the organ has to be removed far back.

When amputation is performed about the centre or behind the glans, great care must be taken in the operation. I have found the formation of lateral skin and fascia flaps very advantageous. The urethra is cut a little longer than the corpora, and slit up along its under surface for a full half inch. The cut margins are accurately united to the edges of the skin flaps, the incision being prolonged backwards for the purpose. Indeed, the urethral opening can hardly be much too free. I pass a No. 12 gum catheter into the bladder and keep it there during the first week, secured by a silk stitch to the mouth of the operation wound.

The question of infection of the inguinal glands is an anxious one. Any implication of these structures renders the prognosis unfavourable. Still, amputation may be performed even in the presence of hopeless glandular contamination, in the hopes of giving the patient temporary relief by removing a local mass of disease, a source of great discomfort and misery.

The question of operating or not upon enlarged glands in the groin must vary with each individual case. Instances

[11] THE LANCET, August 20th, 1887.

may come before the surgeon where all proceedings are hopeless. Many cases may present themselves which are doubtful. I would, however, draw your attention to one condition in which operation is peculiarly unfavourable, namely, when a twofold infection has occurred, and the glands are suppurating as well as implicated in cancerous growth. As a rule, in such cases operation wounds never heal, and a cancerous ulcer in the groin with all its attendant miseries may result from the best executed operation. Supposing you have made up your mind to extirpate the glands you may recollect that the majority lie above the fascia lata, and can be safely taken away from the femoral sheath. I strongly advocate raising a large triangular flap of skin and fascia, so as to expose the whole of Scarpa's triangle, and not to attempt to operate through small or insufficient incisions. The glands must then be cautiously removed. Should the femoral vessels pass through the mass I advise nothing more to be done if it be impossible to remove the glands from the vessels. I have seen the femoral artery and vein taken out in such cases and I have twice seen high amputation at the hip performed under similar circumstances. The result of these cases made me make a careful note never to imitate such proceedings in my own practice. If the lumbar glands are infected the case is very hopeless. It would be quite justifiable in such cases to remove the masses through a trans-peritoneal opening, but the practice would be risky and, I fear, would hardly prevent speedy recurrence by the side of the spine higher up. One course of practice is quite clear. If early glandular enlargement exists at the time of operation a very free removal should coincidently be effected.

The last part of this interesting and important subject is the question of prognosis. Here the usual caution must be inculcated. As a broad rule cases of chronic growth started by local irritation show remarkably good results and I have an impression that the warty papillomatous epithelioma is less malignant than the infiltrating ulcerative type. Another rule which stands good is the fact that if glandular contamination is at all extensive temporary local relief alone can be hoped for. To try to form an estimate of the results of these operations I looked up a number of cases in our hospital notes, but I failed to find the patients at the addresses given and I could not accurately estimate the final results. This is an unfortunate circumstance and the final results of our cases are in hospital practice too often lost in obscurity, yet nothing is of more importance from an educational point of view, as teaching the true value of operative procedures. Accordingly I am not in a position to offer you information regarding the prognosis founded on a large series of cases. Like other instances of epithelioma produced by local irritation extreme chronicity is observed in some instances, and if removal is effected prior to glandular contamination very beneficial and lasting results may be anticipated. I have performed this operation, or assisted in its performance, six times and I have knowledge of what has happened to the cases afterwards. These cases I now shortly relate. I may remark that the diagnosis in each of them was established without doubt and that microscopical examinations were made.

In the first case I have experienced the operation was performed by the late Sir George Humphry and I acted as assistant. As I have intimate knowledge of the progress of the patient afterwards I may shortly relate it. A gentleman, aged about 60 years, had persistent eczema of a gouty nature beneath a phimosed prepuce. He declined circumcision and an ulcer formed which, unfortunately, was treated with caustics—I believe nitric acid. An ugly epitheliomatous sore of the size of a shilling implicating the glans penis was the result. The glands in the groin were apparently not enlarged. The penis was amputated about its centre, the urethra was left long, slit up beneath, and attached to the skin. This gentleman remained well for no less a period than over 10 years. He was hale and hearty and died from affections quite unconnected with the original malady.

The second case was that of a gentleman, aged 57 years. I saw him in July, 1889. He had life-long phimosis and a hard, painful, indurated lump had slowly formed beneath the prepuce. The glands in the groin were apparently not implicated. In this case I was in grave doubts about the nature of the sore. The patient was married with one child but confessed to occasional irregular intercourse. I obtained permission to slit up the prepuce under anæsthetics. When this was done a foul ulcer was disclosed with hard gristly edges. This was dressed with carbolised dressings and iodoform and watched. Portions of the edge of the sore were examined microscopically, but one observer contradicted the dictum of the other. Iodides were administered in full doses, for an eminent consultant, relying rather on the history of the patient, pronounced strongly in favour of syphilis. As time wore on the true nature of the malady only became more apparent and amputation was performed in 1889. The organ was removed flush with the pubes and the urethra was dissected up and brought out in the perineum in front of the anus. This patient died two years ago from "bronchitis." He remained well with comfortable micturition for no less a period than eight years. Micturition through the perineal urethra was always well performed without discomfort.

The third case is still more remarkable. A retired army officer, aged between 50 and 60 years, had long suffered from old syphilis of the penis. The glans was ulcerated, the prepuce was thickened, fissured, and scarred, with whitish patches of thickened epithelium upon it. Indeed the appearance much resembled what one is familiar with in old syphilis of the tongue. This gentleman saw many surgeons and all sorts of remedies, local and general, were applied. At length, from the site of the imperfectly healed ulcer, a mass of epitheliomatous growth sprouted. I removed the organ about the centre, by the lateral flap method, leaving the urethra long, well slitting it up, and stitching it to the skin on either side. The inguinal glands being but slightly enlarged were not interfered with. The operation was done in 1892 and the patient is well, with good micturiting power at the present time, a period of seven years.

The fourth case was that of a man, aged 45 years, who was operated upon in St. George's Hospital nearly four years ago. In his case the disease had commenced beneath a phimosed prepuce nearly 10 years prior to admission and had extended to a great degree, infiltrating the body of the organ. The inguinal glands remained free. In this case the whole organ was removed by splitting the scrotum and detaching the crura. Great trouble was encountered with profuse venous bleeding from a large vein which passed through the sub-pubic ligament and was cut nearly flush with it (dorsal veins of penis). This was ultimately secured by a pressure forceps which was left attached. The urethra was brought out in front of the anus, left about three inches long, and covered by two little flaps of skin dissected up from the perineum. This patient healed well, but his mental condition was serious and on the third day he became insane. I at once got him out of bed and gave him a liberal allowance of wine and good food. In about a week his delusions passed away and he ultimately recovered completely. The other day he came to see us. Nearly four years have elapsed and there is no sign of return of the disease. His micturition power is excellent. The perineal urethra is shrunken and retracted, so that a prominent elevation about an inch in height projects from the surface. He is able to micturite with comfort and even to expel a definite jet of urine away from the body.

The fifth case was in the person of a strong, healthy man, only 40 years of age. A mass of papillary epithelioma had formed beneath a phimosed prepuce. The history was quite uncertain. Amputation was performed and he was quite well three years after. He has gone abroad and I do not know what has become of him.

The last and sixth instance was in the person of a gentleman, aged about 50 years. He had noticed trouble beneath a phimosed prepuce for about two years. The whole penis was converted into a formidable cancerous mass, a sprouting lump of papillary growth projecting from the prepuce. The inguinal and lumbar glands were free. In this case the "complete" operation was performed. He recovered well, with good micturition power. The operation was done too recently to estimate its ultimate result.

In conclusion I would point out that a recollection of these cases will enable you justly to offer great encouragement where it is so much needed. I have an impression that, as in the case of cancer of the breast, an investigation into the results of operations for epithelioma of the penis would show many cases as strikingly favourable in their ultimate results as those I have related. It is for you in your future practice to remember that early operation is the secret of success, and ever to avoid undue procrastination,

or the treatment of conditions on the verge of being cancerous with irritating and inefficient remedies. You will thus avoid reproaches too often justly deserved, and will obtain the confidence and ultimately the gratitude of your patients.

MALARIA AND MOSQUITOES.[1]

BY DR. G. BASTIANELLI
AND
DR. A. BIGNAMI.

(*Translated for* THE LANCET *by* Dr. G. SANDISON BROCK.)

THE suspicion that some relation exists between malaria and mosquitoes is to be found more or less clearly expressed by even the less recent authors, amongst others by the celebrated Roman physician Lancisi. But the question cannot be said to have entered upon its scientific phase until within the last few years, when, with a knowledge of the malarial parasites of man, various investigators directed their efforts to the investigation of the biology of these parasites in their extra-corporeal existence and to the means by which they effect an entrance into the human organism. The constantly negative results of all attempts to discover the parasites in the soil or in the water of malarious places led some observers to the conclusion that their studies should be pursued in another direction. Taking advantage of certain facts observed in the analogous affections filaria disease and Texas cattle fever, two hypotheses were constructed which served as guides in this fresh investigation. As to the first, it was known that in filaria disease the parasite is sucked in with the blood by a particular species of mosquito, within which it completes its life-cycle, and after the death of which it is set free in water. On this fact was constructed one of the many hypotheses suggested by Laveran which was afterwards sustained with much warmth by Manson. In regard to the second — the Texas fever — it had been shown that the disease was caused by a tick which inoculated a parasite of the red corpuscles, closely analogous to that of human malaria, into the blood of cattle. This served as the basis of the other hypothesis.[2] Two indications towards a solution were thus furnished. On the one hand the attempt was made by causing mosquitoes of various species to bite malarious persons, to follow out in them the further development of the malarial parasite as had been done in the case of filaria, and on the other hand mosquitoes collected in malarious localities were made to bite healthy persons in order to see whether the latter would take the fever. The former method led up to the first brilliant results of Ross who, studying the proteosoma of sparrows, succeeded in following out its whole life-cycle in a particular species of mosquito (the grey mosquito). These researches of Ross, it is apparent to everyone, possess an extraordinary importance, since they not only indicate for the first time the forms in which a hæmosporidium develops in the body of a certain species of mosquito, but demonstrate the fact that for a given hæmosporidium such development is only possible in a given species of mosquito, and in no other species, and therefore indicate the necessity of looking for a separate and appropriate species of mosquito to serve for the development of each different species of hæmosporidium. In this way they constitute an invaluable guide to subsequent researches on human malaria. We deem it well to emphasise these points so that no one can suspect our perception of the truth to have been obscured by certain recent polemics. The second method, after a series of attempts which little by little led to a simplification of the problem, has resulted in an irrefutable experimental demonstration that human malaria is a disease inoculated by particular species of mosquitoes.

The two hypotheses referred to as having served as guides in the investigation (namely, that of Laveran-Manson, based on analogy with the filaria nocturna, and the hypothesis of inoculation) appear at first contradictory, since the former led to the conclusion that man is affected through the medium of the water of malarious places (as sustained by Laveran, Manson, and, in the beginning of his studies, likewise by Ross), or even by means of the air; the latter, on the contrary, excludes any such possibility, holding that malaria is a disease exclusively of inoculation. This last view was supported, not only by arguments founded on analogy, but also by a series of epidemiological and clinical facts all tending to exclude the possibility of infection by the other channels so commonly—indeed, one may say universally—believed in. In fact, in the case both of human malaria and of the proteosoma of birds, mosquitoes not only take the parasite from its warm-blooded host but inoculate it afresh into a new one.

For determining the variety or varieties of mosquito adapted to the development of the hæmosporidia of human malaria the assistance of a zoologist was necessary in order that it might be ascertained which were the species predominating in places where malaria prevailed. To this study attention was devoted by Grassi, who pronounced as "suspected" all the species which are found in malarious localities and are not found in healthy ones, and more especially three of these—viz., anopheles claviger, culex penicillaris, and the so-called culex malariæ. With these species, captured in the adult state in a highly malarious locality at the end of the malarial season of 1898, the first case in man of experimental malarial infection was obtained. This result, the importance of which has almost been overshadowed by the mass of evidence brought forward later, produced a deep impression on our minds since it gave us the certainty of being on the right track.[3] The mode in which this experiment was conducted did not, however, admit of an exact determination of the species of mosquito responsible for the inoculation. Only by subsequent researches was it demonstrated that the extra-corporeal hosts of the human malarial parasite are the various species of the genus anopheles. The complete demonstration of this truth is the fruit of the work carried out in collaboration during the past year by Grassi and ourselves.

Of these researches we may give here a brief *résumé* to indicate the present state of the question, and we propose in doing so to occupy ourselves first of all with the æstivo-autumnal parasites. These present two life-cycles, one of which is completed entirely in man and is the cause of the fever, while the other is only initiated in man and is completed in mosquitoes of the genus anopheles. This second cycle is represented by the semilunar bodies, the significance of which has hitherto been a subject of controversy. These forms, as we have demonstrated, originate principally, if not exclusively, in the medulla of the bones, where the young forms are found accumulated; they then pass into the peripheral circulation, where as a rule they are discoverable after the fever has lasted some days; and finally, without giving rise to fever or other symptom of illness, they degenerate and disappear without multiplying and without having any relation to subsequent relapses of the fever. For these reasons we considered them as sterile forms,[4] and sterile they certainly are with respect to *man*. But if blood containing mature semilunar bodies be sucked by mosquitoes of the genus anopheles, the crescents complete in the body of the mosquito a new life-cycle which may be briefly sketched as follows. Some of the crescents are converted into the well-known flagellate bodies; others become round bodies and do not flagellate. From the former the flagella (which, as we have demonstrated,[5] in the forms found in human malaria consist of a filament of chromatin surrounded by a very fine envelope of protoplasm) detach themselves; one of these so-called flagella penetrates one of the round bodies and impregnates it; this impregnated form, after a series of changes to which we shall return later, finds its way into the wall of the middle intestine of the anopheles and is there developed. The semilunar bodies have therefore the significance of sexual forms; adopting the terminology of the zoologist we shall call the crescents "gametes," the pseudo-flagellates or male elements "microgametocites," the single flagella microgametes, and the forms which become impregnated, or female elements, "macrogametes." The macrogametes differ from the microgametocites (in preparations stained by

Romanowsky's method) in having a smaller quantity of nuclear chromatin and the protoplasm more deeply coloured by the blue.

As to the facts of analogy and the observations on which the above conclusions are based, having already cited them in recent writings on this subject, we shall omit them here for the sake of brevity. We refer more especially to the observations of Simond, Schaudin, Siedlecki, MacCullum, and Koch. The impregnated forms—or zigotes—traverse the epithelium of the middle intestine of the anopheles and lodge amongst the muscular fibres. They may, however, develop amongst the cells of the epithelium itself. In either situation they become surrounded by a delicate membrane, and gradually augment in volume till they assume the aspect of a typical sporozoon; the nuclear chromatin divides and sub-divides into a great number of little bodies around which a fine zone of protoplasm is disposed. Segmentation completed, each of these little bodies elongates, assuming a typical filiform appearance; great numbers of such filaments are then seen within the capsule all equally furnished with a distinct nucleus and disposed in various ways around masses of granular substance of greater or less size, in which it is not possible to recognise any structure. These are sporozoites and residua of segmentation. At this point of development, which may be observed in parasites which have reached a very variable size—for instance, in the largest sporozoa of 80μ diameter, or even more, as well as in parasites less than half that size—the evolution of these organisms in the middle intestine is completed. The capsules rupture and the sporozoites are disseminated through the body of the mosquito, and finally accumulate within the cells in the tubules of the salivary glands of the insect. When this has occurred the anopheles becomes capable of infecting a healthy individual with æstivo-antumnal malaria by its bite, a fact which has been clearly demonstrated experimentally. This marvellous life-cycle, which is in perfect accordance with that described by Ross in the case of the proteosoma of birds in the grey mosquito, is not completed in a nearly uniform time as occurs with the forms of the same parasite in the homeothermal host (man), but in a very variable period, lasting at a temperature of about 30° C. from 10 to 12 days, and at a temperature of from 18° C. to 20° C., more than double that time.

These facts being established (we omit details for the sake of brevity) we turned our attention to a study of the same cycle in tertian and quartan parasites, which cycle the preliminary observations made with Grassi had shown us is completed in the same mosquitoes of the genus anopheles. Both the parasites of tertian and of quartan fever have two life-cycles, one completed in man, the other only initiated in man and completed in the anopheles, which might therefore be called respectively the human or fever-producing cycle and the anophelian cycle.

As regards the development of the tertian gametes in the anopheles we shall merely state that it is completed in the same manner as is that of the crescent bodies, but that it differs in some evident morphological characters principally in the first stages of growth, so that only in these is it possible to make a differential diagnosis with certainty between the forms of tertian origin and those of semilunar origin. The duration of the development likewise depends chiefly on the temperature, occupying a period more or less within the same limits as in the case of the semilunar parasites. On this point we have little to add to what we published recently. We may mention, however, that we have noticed also in the tertian parasites the formation of the so-called "black bodies" which are mostly found in anopheles that have been infected for rather a long time (more than 10 days) and generally inside ruptured capsules, although capsules apparently whole are also to be found full of "black bodies" of different forms and sizes, elongated or rounded, and representing probably a product of degeneration of the contents of the sporozoon.

The sporozoites are disposed in the salivary glands similarly to those of semilunar origin. The salivary glands are two in number, each composed of three tubules which join together by means of their small ducts to form a common excretory duct. Of these three tubules the central one differs notably from the lateral ones in being shorter and containing epithelial cells of a hyaline aspect; while the others present cells filled with granular or even filamentous contents, especially at the bottom. At first sight this filamentous substance might be confounded with sporozoites. It is, of course, easy to recognise the sporozoites in coloured preparations in which the little nucleus is clearly displayed, but even in the fresh specimen it is impossible for a practised eye to commit the error when once familiar with the uniform size and typical shape of the sporozoites. In this connexion we should mention that in some cases typical sporozoites are seen in the salivary glands incurved so as to form a ring, strongly recalling the well-known annular forms found in human blood. Drawings of some of these ring-like bodies are given in our recent work, and we consider as quite unwarranted the doubt lately expressed as to their identity with sporozoites by Grassi, who gives no reason for such a doubt.

Whilst the development of the semilunar and tertian gametes in the anopheles may easily be followed the study of those of quartan fever presents considerable difficulties. Although we made many attempts, only in two patients did we obtain positive results, or rather only from these two cases did we succeed in infecting mosquitoes.

In passing we may note that even with tertian and semilunar parasites the anopheles sometimes fail to become infected, although the patients whose blood they were made to suck appeared quite suitable for the experiment. This might be due to many reasons. In the case, for example, of the semilunar bodies—if these are not mature or if, on the contrary, they have already grown too old in their human host—it may happen that no further development occurs; but even when the gametes are adult and mature (as may be ascertained by the facility with which in ordinary preparations they are transformed into flagellate bodies) it may still occur that in some of the anopheles no development takes place. And considering that we have met with some anopheles which were not infected even after having bitten suitable patients four or five times in succession we are obliged to conclude that the reason of the failure must be sought for in a complete immunity which some of these culicidæ enjoy.

Returning to quartan fever, we must say that with some patients constantly negative results are obtained. This led us to think at first that possibly the host preferred by the quartan parasites was not the anopheles claviger, with which in general we had experimented, but perhaps another species of anopheles or one of the culicidæ. But this suspicion was not borne out by other considerations. In the first place tertian and quartan fevers are always, or nearly always, found together in the same malarious localities (the well-known instance quoted by Trousseau being exceptional), thus rendering it unlikely that the host elected by the quartan should be a different mosquito from that preferred by the tertian parasite. In the second place we have had opportunities of observing that in some spots where quartan fever prevails—e.g., in a hamlet near the Tre Fontane—only anopheles claviger and various specimens of anopheles bifurcatus were to be found. We therefore repeated our experiments with the anopheles claviger, varying the conditions, or at least making use of patients who had been suffering from quartan fever for various periods, keeping the mosquitoes at different temperatures, &c. The results were that with recent quartans infection of the anopheles was not obtained. We experimented on at least five patients, some of them with numerous parasites, keeping the mosquitoes at a high or medium temperature and using a great many of them, but always without result. The attempt also failed with patients who had had the quartan fever for many months. On the other hand, we obtained some positive results from patients with very old quartans. One patient who was ill for about a year, whose blood, repeatedly examined, showed only quartan parasites, was bitten by 56 mosquitoes bred from larvæ in the laboratory (which, therefore, could not have been infected previously from man). In eight of these, kept in the warm chamber at 22° C., quartan parasites developed, all the stages of which we were able to follow up to the mature capsules with sporozoites.

The quartan parasite in the anopheles follows the same developmental cycle as the tertian and semilunar. The young forms are distinguished by the characters of the pigment and by their appearance; the adult forms with completely developed sporozoites were seen from 18 to 21 days after the bite. The reason of the negative results must be looked for, in our opinion, in the great scarcity, and in many cases in the absence, of gametes in the blood of quartan patients. It appears as if the quartan parasite had adapted itself so well to the parasitic life in man remaining

in his blood for years, as is well known, in spite of all therapeutic measures, that only rarely, and after a prolonged sojourn in its human host, does it develop those forms which are capable of continuing its life in the outer world. This scarcity of gametes, from which arises the difficulty of infecting the anopheles, explains likewise the relative rarity of the quartan as compared with the other varieties of malarial fever.

It does not appear to us admissible that, to obtain the development of the quartan parasites in the anopheles, a different temperature from that in which the tertian and æstivo-autumnal parasites accomplish their development is a necessity; in fact, nearly all the cases of quartan observed by us in the Hospital of Santo Spirito had contracted the fever in the summer or autumn—that is to say, under the same conditions of temperature and surroundings as the greater number of the tertian and æstival cases.[6] It would, however, be desirable to ascertain what the most favourable temperature is for the development of the quartan parasite in the anopheles. Judging from the observations made in the case above-mentioned, which gave the greatest number of positive results, one would say that the most favourable temperature is about 20° C. But further researches would be necessary before a positive statement could be made.

We have hitherto passed over the study of the first phases of development of the malarial parasites in the anopheles, in regard to which Grassi has recently published a short preliminary note.[7] The results of our observations as far as the semilunar bodies are concerned are as follows. The flagellates form rapidly in the intestines of the anopheles, so that impregnation must occur very quickly, but not for many hours after the anopheles has sucked the malarial blood can any changes worthy of notice be perceived in the round impregnated bodies (impregnated macrogametes). After from eight to 10 or 12 hours (the mosquitoes being kept in a warm chamber at 30° C.) one part of the round body becomes differentiated, forming, as it were, a small segment of a sphere and presenting in the fresh specimen a perfectly hyaline appearance. In the other part of the body the pigment is seen collected. From the hyaline portion there now protrudes a prolongation, likewise hyaline, its extremity rounded or somewhat attenuated, which little by little lengthens out, sometimes remaining quite straight, sometimes curving in a hook shape at its free extremity. At this stage of the development we have a figure composed at one extremity of a cylindrical, thinner, somewhat pointed part, and at the other extremity terminating in a sphere, which latter gradually becomes smaller as the cylindrical part grows until when development is complete it has disappeared. At this point the so-called vermicule is completely formed. As has been said, the pigment in the first stages of formation, lies only in the sphere described, and chiefly round its periphery; subsequently it migrates towards the cylindrical part where it tends to collect. In the well and fully-formed vermicule the pigment is found, at any rate in those seen by us, near to the pointed extremity. The protoplasm does not present an entirely homogeneous appearance, some (two) clear spaces being visible in it.

Studying these various stages of formation of the vermicule by Romanowsky's method it is found that the nuclear chromatin is more abundant in it than in the impregnated macrogamete and is disposed in the form of a ball of thread, the nucleus lying at the rounded extremity. In the protoplasm, which is stained blue, clear spaces are visible which have the appearance of vacuoles. In the first phases of development the chromatin presents the same characteristics and occupies the centre of the pigmented sphere. From this description it is evident that the so-called vermicules of semilunar origin present essentially the same characters as the vermicules of the proteosoma described by Koch.

These different phases, it is to be noted, were not seen by us succeeding each other in the same preparation; but by examining various preparations containing the different forms described we have, so to say, reconstructed the process. On this account we consider it more than probable that immediately the blood is removed from its favourable environment—the middle intestine of the anopheles—the process of formation of the vermicule is arrested. At a later period, after about 40 hours, the parasites are seen to have emigrated to the epithelium or more within the intestinal parietes, where they assume elongated (fusiform) or ovoid forms, recalling the fusiform or ovoid bodies of semilunar origin found in human blood.

This much, then, we now know (leaving out of account morphological details) of the development of the malarial parasites of man in the anopheles. All three species of malarial parasite, distinguishable with certainty from each other, adopt as host the same species of mosquito. Do they preserve intact the distinguishing characters of their species? To this question we have returned an affirmative answer, relying not merely on morphological data—that is, on the possibility of distinguishing in the mosquito the various species of malarial parasite, at any rate in some phases of their development—but also on the results of experiment. In fact, we had seen with Grassi that anopheles, after having sucked blood containing crescents, on subsequently biting a healthy person communicated to him the æstivo-autumnal infection; and recently we have made a corresponding test with tertian parasites showing that anopheles, after having bitten a tertian patient, become capable of inoculating tertian fever into a healthy person. Seeing that we had kept these anopheles infected with tertian blood at a temperature of about 30° C. this experiment allows us to exclude the possibility that the tertian parasite may be transformed into the æstivo-autumnal through the agency of the high summer temperature; in other words, it authorises us to exclude the hypothesis of a *seasonal polymorphism*, as it has been called, of the malarial parasites, by which theory we might think to explain how it happens that after the mild tertian fevers prevailing in the spring there should follow in the beginning of July the summer tertian or the pernicious fevers. Thus even after their passage through the anopheles the species of malarial parasites remain distinct and are not become transformed one into another.

Besides this result our inoculation experiments carried out with anopheles permit us to affirm that *a single infected mosquito* is capable of inoculating malaria into man. The knowledge of this fact has a great practical importance. We may even say more—namely, that a single mosquito by successive bites can infect several people; in fact, on examining some of the mosquitoes employed in our experiments after they had bitten the healthy subject, who had subsequently taken the fever, we have still found sporozoites in the salivary glands and mature capsules with sporozoites in the intestine, proving that, even if at a single bite the anopheles empties all the contents of the salivary glands, the glands may still become affected afresh. And, more than this, since it may occur that two species of parasite may develop in one and the same mosquito—for instance, an æstival and a tertian parasite—the two, as we have proved, remaining distinct, it can well happen that a single anopheles may inoculate a mixed infection—e.g., æstival and tertian. Indeed, it is well known that mixed infections of æstival and tertian fevers are by no means rare in Italy.

In view of these facts recently added to our knowledge, and from which it follows that the parasites of human malaria have two necessary hosts, man and anopheles, the study of a malarious locality and of a malarial outbreak must be approached from a new direction. Thus to explain in a complete manner the course of an epidemic of malaria it would be necessary to study, firstly, the malarial individuals; secondly, the malarial mosquitoes; and, thirdly, the places in which the larvæ of the anopheles develop, or that which constitutes a malarial soil in the traditional sense of the expression. The study of the malarial individuals ought, of course, to be made with the object chiefly of establishing as accurately as possible the time at which they took the infection; then the anopheles of the locality should be examined in order to learn what occurred in them during the same period; and, finally, these two orders of facts should be compared for the purpose of ascertaining what relation might exist between them. Such an investigation we have endeavoured to make since the spring of 1899. until the outbreak of the annual malarial endemic in the district of Ostia, a locality known to be highly malarious, in spite of the improvements which have been carried out there. The following is a short account of the results of this inquiry and of the inferences which we have drawn from them in regard to the practical measures likely to prevent infection.

[6] Grassi considers that the quartan parasites do not develop in the anopheles when the temperature is elevated. This view would be opposed to the epidemiological facts stated above.

[7] According to Grassi the zigotes assume very various forms "more or less recalling the radiæ, sporocysts, and cercaria of the trematodes," &c.—Atti dell' Accademica dei Lincei, Sept. 17th, 1899.

With respect to the study of the malarial patients we may say at once that the observations made this year go to confirm what we already knew from the experience of preceding years. In winter as a rule only *relapses* of æstivo-autumnal, quartan, and tertian fever are observed. As the season advances the relapses of æstivo-autumnal fever become more and more rare, until in the spring it is most difficult to find a patient with crescents; indeed, in the district of Ostia, notwithstanding repeated search, we did not succeed in finding a single case. On the other hand, relapses of tertian and quartan continue to occur right through the spring up to the commencement of the new malarial season, which begins in the first week of July with a sudden increase in the number of patients, among whom, besides many common tertians, are found the first cases of the new season's summer tertian. During the spring some rare cases of first attacks of common tertian are met with. These have been perhaps rarer this year than in past years. But although the possibility undoubtedly exists of contracting a primary infection of common tertian in the spring the *fact* remains that the malarial season proper, with its fresh outbreak of primary attacks, does not commence till the beginning of July and does not terminate till the end of the autumn.[8] This holds good for all the varieties of malaria as much for the common tertian as for the summer-autumn and the quartan.

A methodical examination of the patients admitted during that period to the Santo Spirito Hospital has led us to the same conclusion. From the first half of April till the first half of May the admissions to the bospital were relapses of tertian and quartan and, besides, four cases in which crescents were found. From May 21st to June 20th we examined the blood of 42 tertians, of five quartans, and of only one patient with crescents. The tertians, except two or three, had all had fever during the previous year; the quartans were all relapses; the patient with crescents had suffered from fever since the previous June. From June 20th to June 30th the patients were very few—seven tertians, one quartan, and five æstival—of which latter three were cases of first attack and two were cases of relapse. The last two patients had suffered from fever at irregular intervals since October of the previous year and showed crescents in their blood. At the beginning of July began, as usual, the influx of patients with primary infections—in fact, during only nine days (from July 1st to July 9th) we examined the blood in 26 cases of common tertian, 17 of which were, however, those of patients who had suffered from fever in the previous year and in whom, therefore, it was not possible to be certain whether we had to do with a relapse or a re-infection. During the same period the patients with æstivo-autumnal fever numbered 27, of whom certainly 17 had primary attacks.

From this examination of the patients admitted to the Santo Spirito Hospital we therefore drew the same conclusions as from our inquiry among those in the Campagna of Ostia. The only difference is that among those received into Santo Spirito Hospital we found some crescents (very rarely, it is true), while during the same period we found none in the Campagna. This may have been owing to the fact that only the peasants which have the gravest forms of relapse and the largest number of parasites take refuge in the hospital, whilst those which remain in the Campagna have so few parasites that the crescents are very difficult to find.

Let us now turn to the observations made contemporaneously on the anopheles, premising that in the whole district of Ostia (as in all the other places where, as, for instance, at Porto, the first tentative experiments with mosquitoes were made several years ago) the mosquito which almost exclusively prevails is the anopheles, and more especially the species anopheles claviger. In the months of March, April, and May we found anopheles in the houses, in the stables, and also under the bridges, generally with mature ova which for the most part were deposited after the mosquitoes had been brought to the laboratory. We found the same at Porto and at the Tre Fontane. In the month of June we began to find anopheles infected with malarial parasites, but only in small proportion—on an average about 3 per cent. of those caught in inhabited localities. Of those, on the contrary, caught in localities far from any habitation—for example, in a house near the small lake at Castel Fusano, in which there was at the same time a perfect swarm of larvæ—none were infected with the parasite of malaria, although they frequently contained other parasites—as, for example, a special brown sporozoon described briefly by Grassi and us, filariæ of at least two species, &c. It is thus evident that the few malaria-infected mosquitoes met with had taken the parasite from patients suffering from relapses of fever in whose neighbourhood they were living.

During the harvest season in June and beginning of July the number of infected mosquitoes remained very much the same. Wherever people congregated there also the anopheles gathered. For instance, the harvesters slept in the open until June 22nd, but on that date a large company of them were housed in a big granary which served them as a dormitory. On the 23rd, after a long search, a single anopheles was found in the granary; on the morning of the 24th eight were captured; and on July 1st no less than 366. Of these 90 were examined and only three were found to be infected, one of them with mature bodies and sporozoites in the intestine. Subsequently the number of infected anopheles increased at a rapid rate. It is instructive in this connexion to study what took place in an encampment of labourers (corn-threshers) near Ostia (on the Calabresi estate). The work there commenced on June 21st and continued till the beginning of August. About 42 men took part in it regularly (besides others of the floating population who could not be taken into account). Of these some had fever in the previous year and until the work commenced had suffered from relapses of tertian; in none were crescents found. Naturally we cannot exclude the possibility, however, that one or other may have had an extremely small number in his blood. Of the anopheles collected in the huts of seven of these people on July 1st two out of seven were found to be infected; of those collected on the 9th and 10th two out of 17; of those captured on the 17th 15 out of 32, or about 40 per cent.; and on July 20th the number of infected anopheles had risen to 11 in 17, or about 64 per cent., some of them presenting ruptured capsules and mature sporozoites. It is to be noted that the anopheles captured during the same period in the stables or at a distance from human habitations were, as a rule, not found to be infected. At the end of July and the beginning of August nearly all the men who had slept in these huts were affected with æstivo-autumnal or tertian fever. Evidently they had been infected by the mosquitoes which had invaded their huts and which had in their turn taken the parasites from those amongst the labourers who were suffering from relapses of fever. The progressively increasing number of anopheles found infected explains in the clearest manner, it appears to us, the final outbreak of the disease amongst nearly all the labourers.

It would thus appear from the above observations that the outbreak of the malaria endemic in its severe form at the beginning of July can be satisfactorily explained by the presence of anopheles which have become infected by the cases of fever relapses which are to be met with in May and June. Certain difficulties, however, present themselves to the mind which we cannot for the moment easily overcome. For instance, how are we to explain the great number of cases of æstival fever in the beginning of July, so many of which are certainly primary attacks, whilst in June the patients through whom the mosquitoes must have become infected had, so far as one could ascertain, the tertian variety of fever? It may be that the existence of crescents in some of these patients escaped our notice, a thing easily possible, since part of the population was a fluctuating one. But, even granting this, it is evident that in order to clear up the difficulty completely further researches are necessary.[9]

[8] Celli and Delpino: Contributo allo Studio della Epidemiologie della Malaria (Supplemento al Policlinico, Sept. 1st, 1899).

[9] The most common form of mixed infection, according to our experience, is that of æstivo-autumnal and tertian. The two kinds of infection do not manifest themselves simultaneously in the patient, but succeed one another; in fact, we have frequently seen patients with æstivo-autumnal fever, although residing in a locality free from malaria, suffer a relapse of common tertian, and, further, observed patients with æstivo-autumnal fever, in whose blood the æstival parasites were numerous, show also a very few tertian parasites without the clinical course of the disease being modified. These facts convince us that many of the patients who present themselves at the hospitals at the beginning of July with æstival infection apparently pure have been in reality inoculated likewise with tertian parasites. But the æstival infection develops first and alone, first of all because, as we know, its period of incubation is in general shorter than that of tertian fever; we also know that in the mixed infections one of the species of parasites always predominates and gives its stamp to the clinical picture, the other species developing when the first is temporarily or definitely exhausted. These considerations, together with what we know of the

Naturally, the new malarial season once fairly started, the continuation of the epidemic is easily explained by the passage of the hæmosporidia from man to the anopheles and from the latter back again to man.

Finally, coming to the third subject of our researches—namely, the study of the localities in which the anopheles develop—it is necessary to recognise the fact that at Ostia, in spite of all the recent improvements, there exist all the conditions favourable to the production of the malarial mosquito. The district of Ostia is intersected by a dense system of canals which collect the water of the lowest levels and convey it to the elevating machines by which it is emptied into the sea. This system of canals consists of a main channel with secondary channels leading into it. Now in all the secondary canals, and in the part of the principal canal farthest from the machines, where there grows a rich vegetation of reeds and algæ, we found, from the beginning of June onwards, an immense number of larvæ of the anopheles. The larvæ were absent in the part of the principal canal nearest to the machines, where the vegetation was scanty or wanting, and where the action of the machines kept up a considerable current. Everywhere else, wherever the water moved very slowly or tended to stagnate—which in summer is almost the rule, because the machines on account of the low water-level only work in an intermittent way—the development of the larvæ was most vigorous. Another very favourite breeding-place of these larvæ is in the neighbouring small lake on the estate of Castel Fusano. We found larvæ very numerous everywhere from the beginning of June onwards till the middle of July, when they were fewer; and they were again numerous there and elsewhere in the Campagna, especially in the small lakes at Porto, in the months of September and October up to the time of the last rains. These facts explain in an entirely satisfactory way why the drainage works at Ostia, in spite of the removal of the marshes, have not, from a hygienic point of view, achieved their object.

And now, what practical conclusions can be drawn from these data with respect to measures of prophylaxis against the infection? These are abundantly evident. Indeed, everyone in Italy who has made a study of the subject in the light of these new researches has insisted from the first that the careful treatment of the malarial patient constitutes one of the principal tasks of social hygiene. We ourselves, in a short article published last April, were careful to note that the energetic treatment with quinine, from the commencement of the infection, of the æstival fevers not only reduced the dangers of relapses to a minimum, but had evidently a great importance for general prophylaxis, since the parasites by its means could be prevented from developing into those forms which continue their life in the anopheles. The treatment of the malarial patient ought, therefore, to be carried out systematically and energetically in the same manner as is practised when countries are invaded by other epidemic and contagious diseases. And yet we see here in Italy the peasants of our country districts suffering for years from the disease abandoned to themselves and continually disseminating the infection. This could be put to the test of experiment by treating all the patients in some circumscribed area systematically throughout the winter and spring from the date of their first febrile attack (thus reducing relapses to a minimum) in order to see subsequently what the behaviour of the infection might be in the new malarial season—that is to say, from the beginning of July onwards.

We urge that the treatment should be carried out energetically from the date of the first febrile attack because we know that quinine, although it can interfere with, and even prevent, the development of the young crescents, has no evident action on those already matured. Indeed, we have several times seen since July of this year that crescents from the blood of patients under the influence of quinine may complete their life-cycle in the anopheles in the normal manner.[19] It is true that an ideal prophylaxis would be attained by removing the conditions which are necessary to the development of the anopheles in the malarial areas. Limiting ourselves to a consideration of the district of Ostia which we have studied we hold that such an object might, at least in part, be obtained by keeping the canals clear of the excess of vegetation, by removing the obstacles which in some of them retard the flow of water, and by working the elevating machines more regularly so as to maintain a certain degree of velocity in the current. By these means the immense production of the larvæ of the anopheles might be at any rate diminished. But it is not our intention to occupy ourselves with the question as to the method best adapted for attaining the end in view; this is a task which does not concern us. We confine ourselves to indicating the fundamental points which ought to guide those who devote themselves to a practical solution of the problem, those being a knowledge of the localities in which the larvæ of the anopheles live and develop and of the reasons why they thrive in these places.

Note.—We have stated in the above paper that nearly all the quartan patients observed by us in the Hospital of Santo Spirito had contracted the fever in the summer and autumn—that is to say, under the same conditions in regard to temperature and surroundings as are required for the development of æstivo-autumnal and the greater number of tertian infections—and we have inferred from this that the anopheles must in general become infected with quartan parasites under the same conditions of temperature as those under which they become infected with crescents and the gametes of tertian fever. This is not opposed to the fact which has long been known that the majority of quartan cases are met with in our hospitals in the autumn and winter—that is, in the cold season. Indeed, if the history of these patients be closely inquired into it is found that in general they have been residing in the Campagna during the hot season and have taken the disease in a form at first not characteristic of the quartan type, but that subsequently a relapse occurred, occasioned by the cold weather, and that this relapse ran a typically quartan course.

Rome.

greater pathogenic power of the æstival parasites, can be utilised for explaining, at any rate in part, the facts above mentioned.

[19] The same facts have been noted independently by our colleagues Gualdi and Martirano.

VOLKMANN'S ISCHÆMIC PARALYSIS; ITS TREATMENT BY TENDON-LENGTHENING.

BY HERBERT W. PAGE, M.C. CANTAB., F.R.C.S. ENG.,
SURGEON TO ST. MARY'S HOSPITAL; EXAMINER IN SURGERY TO THE UNIVERSITY OF OXFORD.

IT is probable that few only are familiar with the title of this paper. Examples of the disease are happily rare, and the name is not to be found in our text-books. Yet the affection is one of serious gravity and hitherto has been found little amenable to treatment. I propose, therefore, to record a case in which great benefit has accrued from lengthening the contracted tendons, not only by enabling lost movements to be regained, but also by restoring the affected muscles to a seemingly more healthy state. In describing the case I hope to bring the salient aspects of the disease forward and to point out the causes which induce it. Volkmann's own account of it may then be considered.

A boy, aged four and a half years, was first brought to my notice and admitted under my care in St. Mary's Hospital on Nov. 5th, 1898. In August he had fallen on his left elbow and sustained a transverse fracture of the lower end of the humerus. Separation of the lower epiphysis was not, however, excluded from the diagnosis. For some inscrutable reason the limb was put up in the flexed position with anterior and posterior splints on the forearm. All seemed going on well the next day and the splints were not disturbed, but when the child was brought to the casualty room a few days later there was found to be total loss of power of the fingers and wrist. Immediately below the fold of the elbow the pressure of the end of the splint had caused a superficial slough, which became detached in the course of four weeks and left an open wound which healed by granulation. In the meantime the limb was secured on a single posterior splint, and when this was abandoned at the end of four weeks the parents were instructed to manipulate and rub the arm, for an increasing tendency to contraction of the fingers had been noticed and the wrist also was becoming more and more flexed. On one occasion under an anæsthetic a fruitless attempt was made to straighten the fingers and hand. Such was the story related to me.

When I first saw the child, three months after the accident, the arm was supported in a flexed position midway

between pronation and supination. The site and surroundings of the scar below the elbow were exquisitely tender, and there was tenderness of the whole anterior surface of the forearm also, so that the child could hardly bear to have his limb examined. There was extreme flexion at the wrist and the fingers also were flexed into the palm. So great indeed was the contraction of the flexor muscles that extension of both fingers and wrist was hardly possible even with much force, but the joints were clearly unaffected. Strong flexion of the wrist had but small influence over the extensibility of the fingers. Anæsthesia was partial only, involving the ulnar distribution in the hand, and there was some suspicion of wasting of the first dorsal interosseus. The flexor muscles felt peculiarly unyielding to pressure and decidedly firmer than natural. With the exception of the nervous affection which has been named I could detect no median, ulnar, or musculo-spiral paralysis, and I attributed the slight ulnar paresis to local injury to the ulnar nerve at the site of the fracture, and possibly to the pressure of callus which was to be felt at the lower end of the humerus. My own belief was that there had in reality been a separation of the lower epiphysis. An examination under an anæsthetic threw no further light on the condition, nor was the contraction of the flexors in any way lessened. That this deplorable state of things was in some way the result of splint pressure there could be no doubt, and in all its aspects the case was exactly like two other cases which I had had the opportunity of seeing.

This, then, being the state of the limb, and massage, electricity, and movement being each and all without remedial influence, it was thought that lengthening of the flexor tendons gave fair promise of benefit, and accordingly, on Dec. 20th, 1898, the tendons having been exposed by raising a rectangular flap immediately above the wrist were each in turn split longitudinally, severed to right and left at the opposite ends of each incision, extended, and sutured with the finest silk in the usual way. This part of the procedure was by no means easy. The diminutive size of the tendons in the small arm of a little child made it very difficult to fix the sutures, and I had slight hope that successful union would follow. I was not sure, moreover, that in every instance the divided tendon was joined to its own partner, and it is highly probable that a superficial flexor may have been attached to one of the deep tendons. This was quite unavoidable. In any case I thought that it would not materially affect the ultimate result. Exposure of the muscles enabled us to judge of their condition. They gave the impression of being stiff and unyielding, firmer than natural, and as if their structure had been changed—not at all as if they were affected by some spasmodic contraction of nervous origin. This, indeed, was their state as I have already endeavoured to describe it when estimated by manipulation through the skin, and it suggested that there really was some alteration in the physical constitution of the muscle fibres themselves and probably also of the connective tissue around and between them. The hand and arm were now secured in the flexed position, and the wound healed by first intention. After a fortnight we ventured to move the child's fingers and it then appeared that considerable union of tendons must have taken place. Tentatively, therefore, day by day, and each day with increasing boldness, both arm and fingers were extended, and at the same time massage and electricity were brought to bear upon the affected limb. Improvement was very slow and the patient left the hospital in February, 1899, with a feeling of disappointment on our part that it had not been more decided, but with the hope that much might yet ensue. The child was to attend as an out-patient for electrical treatment and from Dr. Wilfred Harris, under whose care he has since been, I learn that there was at first very decided reaction of degeneration, but that recently this condition is not so marked. Reference will be made again to the electrical phenomena when considering the causation and underlying structural changes of this remarkable form of paralysis.

I next saw the child at the end of July and was happy to note distinct signs of improvement. That, with the one exception of the forefinger, the tendons had united there could be no doubt; tenderness of the limb was much less and the wrist and arm could be extended without anything like as much associated flexion of the fingers as had been remarked when the patient left the hospital. The mother was urged to continue her attendance at the hospital with every hope of still further improvement. When seen again at the beginning of October so great had been the progress that it was hard to believe that we had the same limb before us. All tenderness had gone. The forearm could be completely extended, the wrist and the hand could be voluntarily put in the extended position, flexion of the fingers was easy, and the little fellow could make a fist. The forefinger only was at fault, the flexor profundus alone acting on it. Furthermore, the muscles of the arm seemed to have lost that peculiar sense of resistance which had formerly characterised them. I had no longer any hesitation in holding out a much more favourable prognosis as regards the usefulness of the limb, believing that still greater improvement would surely be noticed as the limb in the natural process of growth increased in size. I feel justified, moreover, in placing the case on record now, sufficient time having elapsed to admit of a fair estimate of the result of operation.

Turning now to a consideration of the causes which induce this form of paralysis there is a consensus of opinion that in some way or other it is the prolonged pressure and fixation of the limb in splints which give rise to it. Thus Anderson[1] says: "It is a result of prolonged immobilisation of forearm fractures by any form of apparatus that intercepts the free circulation of blood through the muscles and nerves of the part." He seems in this extract to accept the view put forward by Volkmann as to the ischæmic origin of the affection and that it is not due primarily to a nervous lesion. On this point there is room for difference of opinion and the opinion of Volkmann himself may first, and very rightly, engage us. I find that the earliest reference made to it by him was in a footnote to a paper on inflammation of the muscles where he says[2]: "The severe contraction of the hand after too tight binding of the forearm after fracture belongs in part in all probability to such a process of inflammatory muscle-contracture and not to primary nerve-paralysis from pressure. The resultant *main en griffe*, as it is termed, has a very bad prognosis. The contraction of the fingers and hand remain so pronounced in spite of electrical treatment, passive motion, and forcible extension under an anæsthetic that amputation may in the end have to be resorted to. Complete recovery or even marked improvement I have never seen; and only in one instance, after unwearied trouble and long-continued treatment, have I noticed a diminution of the contracture and slightly better movement. The contracture comes on very rapidly and in a few weeks may attain to such a degree that the finger-nails bore into the flesh of the palm. In paralytic contracture no such acute contraction is ever seen." The next paper to which I will refer is by Kraske,[3] a pupil of Volkmann, and since distinguished in other spheres of surgery, in 1879, on the changes found in transversely striated muscles after exposure to extreme cold. His observations are based on the microscopical examination of the muscles of two legs which had been amputated for gangrene the result of some hours' exposure to extreme cold. He described widespread necrobiosis of the contractile substance, complete loss of the nuclei in many of the primitive fasciculi, and the absence of striation and a granular appearance of the fibres. Reparative changes were also distinctly visible, and then he writes: "The appearance of the muscle tissue corresponds closely to the changes which are seen in the muscles of a limb which has been for a time rendered bloodless by circular constriction. The ischæmia, induced in the one case by lowered temperature and in the other by circular constriction, determines a partial necrobiosis of the contractile substance, to which is added some precedent inflammation in the perimysium internum and regenerative processes in the surviving muscle fibres."

It is unnecessary to dwell further on the microscopical changes which are to be found in muscles which have been deprived of blood. The clinical phenomena are here of more concern, and a précis may be given of the conclusions at which Volkmann had himself arrived and which are to be found in his paper on "Die Ischaemischen Muskellähmungen und Kontracturen."[4] He there relates how the observation of a considerable number of cases in the course of several years had led him to believe that the paralysis and contracture, the result of too tight and too long fixation, were due to a direct effect upon the muscles themselves rather than to any nerve lesion. The following are his propositions: 1. The paralysis and contracture are of ischæmic origin and

[1] Fingers and Toes, p. 65.
[2] Krankheiten der Bewegungsorgane, 1875, p. 846.
[3] Centralblatt für Chirurgie, 1879, vol. vi., p. 193.
[4] Centralblatt für Chirurgie, 1881, No. li.

dependent on the deprivation of arterial blood. The simultaneous venous congestion which is often seen appears only to hasten the onset of the paralysis. 2. The paralysis depends on the fact that the muscle fibres perish from prolonged want of oxygen. The contractile substance coagulates, breaks up, and finally disappears. Rigor mortis is in fact induced in the affected muscles. 3. It is especially characteristic that paralysis and contraction arise simultaneously, not as in paralysis of nervous origin where contraction is a later phenomenon and of gradual onset. 4. From the earliest moment and in quite recent cases the muscles assume the state of rigor mortis and there is the greatest obstacle to extension of the limb. 5. By contraction of the material thrown out in the attempts at repair the rigidity and contracture of the limb are made worse. 6. Ischæmic paralysis and contracture of the same nature are also seen to follow the application of Esmarch's bandage, injury to the greater vessels, and exposure to extreme degrees of cold. 7. The degree of paralysis and contraction depends upon the length of time that the blood-stream has been arrested. If the ischæmia has been extreme the most serious consequences may follow in half a day, or even less, while symptoms of a high grade of severity may result from slight constriction and pressure of several weeks' duration. This is most common after fractures of the radius. 8. The prognosis is bad, and in the worst cases involving the hand and fingers the condition is absolutely irremediable. It is better in the case of the lower limb, for here tenotomy may be practised. The slighter cases may be benefited by energetic treatment with massage, &c. 9. Mechanical treatment is practically useless. In recent cases one would endeavour to extend the muscles under an anæsthetic; but in those of long standing any attempt to do so would be found to break the bones or tear the tendons before the muscles would yield.

So far Volkmann, in unavoidable abbreviation, and with the single exception of Anderson's work already referred to I have failed, even with the invaluable help of Mr. Plarr, Librarian of the Royal College of Surgeons, to find aught else in medical literature upon this interesting subject. That this singular form of paralysis is due to the combined influences of pressure, fixation, and ischæmia there can hardly be a doubt, nor is there any doubt that my own case was an example of it. The rarity of the condition is probably one reason why so few cases have been placed upon record; but it is not unwarrantable to assume that some have not seen the light because, in the words of Anderson, the paralysis is "a reproach to surgery, since a careful observation of the hand and fingers during the use of splints will always give due warning of the danger."

It is not, however, by any means so certain which are the structures upon which continuous pressure exerts this injurious influence. In the observation of my own case I could never believe that it was simply a nerve lesion with which we had to do. The slight ulnar paresis was obviously the result of a trifling injury to the ulnar nerve at the site of injury to the bone, and there was no reason for thinking that the pressure of the splints could have been specially exerted upon this one nerve. If upon any, the median was surely more exposed to pressure, but there was no special evidence of injury to it, and as pointed out by Volkmann the simultaneous origin of the palsy and the contracture was altogether unlike the effect of gross lesion to a nerve trunk. But the electrical observations of Dr. Wilfred Harris show indisputably that nerve elements had not escaped injury. After describing the reaction of degeneration which he discovered, he says, "Any ischæmic condition would, I imagine, damage the nerve-end-plates as well as the muscle and one might expect, I should think, some reaction of degeneration." Mr. Anderson tells me that this view coincides exactly with his own as given in a previous quotation. Dr. Harris adds in a later communication: "The fact of the great reduction to faradaism in the flexor muscles when I first saw the case suggested to me a nerve lesion, perhaps intra-muscular, and does still, since in acute myositis there are no electrical changes until the late stages when atrophy, if any, sets in. Erb, too, states positively in his book that primary muscular conditions do not cause reaction of degeneration, which is in his opinion proof of nerve lesion. But I know nothing of ischæmic myositis and probably Erb did not either and the reactions may very well be a part of the condition as you suggest. The obvious answer to the difficulty would I think be supplied by experiment." I have ventured to repeat here what Dr. Harris has written to me, for he speaks with an authority on such matters to which I cannot pretend. But nothing that he tells me is, I believe, opposed to the view which I would provisionally hold as to the causation of this particular form of paralysis and contracture, that it is not primarily or even in the main due to a nerve lesion but that it is due to the combined effects of pressure, immobilisation, and greatly diminished blood-supply therefrom upon the muscular elements, the connective tissue elements, and the nervous elements which are met with in every muscle throughout the body. That pressure alone, or immobilisation alone, or deprivation of blood alone could bring about the results which are seen is not nearly so likely as the combination of all three, and there is no part of the body on which they can be so readily brought to bear as in the case of the forearm bound up and negligently left bound up after fracture. May the publication of this case be the means of making the evil consequences of such ill-treatment more widely known.

Lastly, as to the tendon-lengthening which was practised here. It seemed to me that it offered the best chances of amelioration of the distressing condition, and from personal experience of it in other instances and for other purposes I felt that the operation was one upon which we might rely. Originally performed and recommended, I believe, in this country by Anderson, and a year later in America by Keen, the operation has become a recognised procedure of much value in surgery, and has doubtless been used by many surgeons. Keen[5] employed it in a case of post-hemiplegic contracture of the flexors of the fingers in a lady 25 years of age, and lengthened four tendons of the deep flexors, five of the superficial and those also of the two carpal flexors, of the flexor longus pollicis, and of the palmaris longus with some measure of success; and Anderson[6] records a case of a girl, aged 17 years, with flexor contraction the result of some injury to the arm in childhood for whom he lengthened the tendons with much benefit. I am further indebted to my friend Mr. Anderson for the opportunity of reading the accounts of two other cases by Dr. Colgan and Dr. Wilson respectively, but they have no special bearing upon the subject of tendon-lengthening in such a condition as was seen in my own case. Akin to it, though owning a different cause, were the cases of Anderson and Keen; but there is, I believe, no case on record in which it has been practised in Volkmann's ischæmic paralysis. The result has far exceeded expectation, and I take it that the great improvement is due not alone to the mere fact that the tendons have been made longer, but that by their lengthening an increased range of movement has been made possible in the affected muscles. Muscles are meant for movement, and movement is an essential element in the treatment of any such affection as the peculiar contracture seen in this disease. Massage and electrical stimulation are also without doubt of inestimable value, but they are likely to fail of their purpose unless some movement is possible at the same time. At any rate, speculation apart, the result of the operation in this instance has been so satisfactory as to justify me in commending the adoption of the same method to the notice of surgeons.

HYPOTHERMIA.[1]

BY E. B. HULBERT, M.D. DURH., M.R.C.S. ENG., L.R.C.P. LOND.

A MAN, aged 36 years, married, the father of three children, was admitted into University College Hospital under Dr. Charlton Bastian (whose clinical clerk I happened to be at the time, and for whose kind permission to make use of the notes of the case I am deeply indebted) on April 16th, 1887, complaining of drowsiness and occasional frontal headache of about two years' duration. He had had scarlet fever when he was a lad and soft chancre ten years before coming under observation, but he denied syphilis. There was no history of nervous disease in the family. He

[1] Being a contribution to a discussion on Temperature in Health and Disease, read at a meeting of the Windsor and District Medical Society on Dec. 20th, 1899.

had been for some years a chemist's assistant, but had latterly been dismissed from his situation in consequence of his marked drowsiness, which at times led to his falling asleep over his meals and when at work, and because he was not always responsible for his actions. Thus on one occasion he was found on the doorstep of a strange house far from home, and on being questioned could give no account of himself and had no recollection as to how he arrived there.

As the man remained in the hospital, with the exception of about ten weeks, until his death on Jan. 2nd, 1888, the notes of the case are naturally voluminous, and the following epitome of his leading symptoms may suffice. Delayed cerebration; occasional mild delirium, diurnal or nocturnal, and at times of a restless type; speech slow and scanning; the skin temperature was obviously depressed; pin-point pupils, reacting to accommodation but not to light; knee-jerks and ankle clonus were absent; no definite spasms or paralysis, either of motion or sensation, until a late period in the case, when generalised twitching movements of the limbs and face occurred; during the same time there was noted want of control over the sphincters; the pulse was regular, of fair volume, the rate varying, directly as the temperature, between the extreme limits of 36 and 170 per minute; the respirations also varied in the same manner from 10 to 48 per minute and at the close were of the Cheyne-Stokes type. The somnolence, always present, was variable in degree but increased as time wore on, and the patient finally died in a comatose condition. The diagnosis made was that of some diffuse degenerative change in the brain, possibly sclerotic in character, and beginning chiefly in the pons and medulla

A most careful post-mortem examination was made and numerous microscopical sections were cut from the cerebrum, cerebellum, pons, medulla, &c., but no gross lesion was discovered in any part of the body.

The interest of the case is chiefly centred in the records taken of the temperature, which was taken on 88 days, commencing on Oct. 5th, 1887, several observations, even as many as 11, being made daily; on only 18 days was the temperature found to register above 98·4° F. The rectal thermometer, which was used for the majority of the readings, was made by Hawksley and was very carefully compared with a standard instrument registered at Kew, made by Casella, and great care was taken to avoid erroneous observations, thermometers being not infrequently placed simultaneously in the mouth, the rectum, the axilla, and even in the urethra. From Oct. 6th to the 16th inclusive the temperature was not accurately recorded, as the ordinary clinical thermometer used was not marked below 95°. The same happened on Nov. 2nd and 3rd, and again from Nov. 9th to the 14th; the rectal instrument on this date recorded 83 3°, and on the same day, without obvious cause, the temperature rose 12·6° in nine consecutive hours, reaching 95·9°. Two days later it sank 13° in 16 hours, the thermometer left in the rectum for half an hour marking 82·3°. On the next day the temperature was slightly lower, and on the following day the minimal temperature in this case was recorded—viz., 81·6° in the rectum (half an hour's observation)—and simultaneously a surface instrument placed on the chest-wall for two hours registered 75·5°. At this stage a hot bath was given, the temperature of the water being gradually raised from 98° to 105°, and the patient's temperature rose 13·1° in 67 minutes and 19 5° in 18 hours. It then became slightly raised above normal for a day or two and again descended, a reading of 90·2° (skin of the chest one hour) being obtained on Nov. 21st. The descent continued with fair uniformity, successive readings of 91·5° (axilla), 89·1° (axilla), 88·3° (rectum), and 85 7° (rectum) being obtained. An hour spent in a hot bath again produced a rise of 13·6°, but the effect was only temporary, 85·5° (rectum) and 85 3° (rectum) being noted. Here the temperature rose somewhat rapidly, and shortly after death marked 104·8° in the rectum.

The literature on the subject of subnormal temperature appears, on the whole, to be scanty, and it is certainly, according to my experience, widely diffuse. A brief epitome may, therefore, not be entirely out of place.

Erichsen[2] says that in fracture of the lower cervical region the temperature may rise to 111° or may sink to 81°, but that the cause is not well understood.

Roberts[3] enumerates amongst the conditions producing subnormal temperatures shock, collapse, severe injury to the upper part of the spine, some diseases of the brain or spinal cord, starvation, severe hæmorrhage, and some chronic wasting diseases—e g., cancer. Regarding cholera, he says that in the stage of collapse the temperature in the mouth ranges from 79° to 88°, in the axilla from 90° to 97°, but that it reaches a much higher level in the vagina and rectum. Also, "a very low temperature has been noted in carbolic acid poisoning and in sclerema neonatorum." He states, "Should the temperature fall below 93° death almost always results."

Russell Reynolds[4] corroborates certain of these statements.

Bristowe[5] says: "In collapse—the result of severe injury—the temperature even in the rectum may fall (Wagstaffe) as low as 82·15°."

Quain[6] states: "A temperature of 71·6° has been observed in sclerema neonatorum." And again, "The whole range of temperature within which life can well be maintained is comprised between 90° and 110°.

Landois and Stirling[7] mention Löwenhardt as having found that "in paralytics and in insane persons several weeks before their death the rectal temperature was 86° to 87·3°." Also, "Beckterew found in dementia paralytica before death 81·5° in the rectum; the lowest temperature observed and life retained was in a drunken person—75·2°[8] (Reinke, Nicolaysen)."

Fagge[9] says: "A great lowering of temperature by *force majeure*, as Liebermeister terms it, is well seen in persons picked up insensible in the streets during cold weather. Cohnheim alludes to cases of this kind in which the thermometer in the rectum has not risen above 86°, 79°, or even 75°. The pupils are then dilated[10] and sluggish, whilst the pulse and the respiration are greatly reduced in frequency, but unless things have gone too far for recovery to take place such persons under suitable treatment regain their normal temperature in a few hours, or even pass into a condition of reactive pyrexia." Regarding the stage of collapse in cholera he says: "According to Goodeve a thermometer placed in the mouth indicates from 79° to 82°. In the axilla, however, the temperature is seldom below 93° or 94° and in the rectum or vagina it rises through the period of collapse, reaching 100°, 102°, or even 104°."

Gould[11] quotes a case recorded by Duffy in which the temperature in the mouth and axilla marked 84°. The patient was a negress, aged 35 years; she aborted, and death took place on the following day.

Osler[12] treats the subject at greater length. Amongst conditions giving rise to a subnormal temperature he refers to: (*a*) Acute alcoholism, especially when aggravated by exposure to cold. Thus are explained the lowest reported temperatures. He mentions a patient who was admitted under these conditions with a temperature of about 75°; ten hours later the temperature had not risen to 91°. (*b*) Cerebral hæmorrhage. "Here it is often subnormal" (Bastian). He quotes a case in which it sank below 95°. (*c*) Heat exhaustion, especially when combined with physical exertion. It may be as low as 95° or 96°. (*d*) Acute tuberculosis. (*e*) Ague (cold stage). The skin temperature may be low. (*f*) Pernicious malaria—the algide stage. (*g*) Chronic tuberculosis. He quotes a case in which the temperature was 95°. (*h*) Tuberculous meningitis. At the close the temperature may be as low as 94°. (*i*) Uræmic convulsions—after the attacks.

Finally, Wunderlich, in his monograph on Medical Thermometry, published by the New Sydenham Society, as the result of 16 years' assiduous work in this field, deals still more elaborately with the subject. He says: "Exceedingly low temperatures are very commonly met with in the following: In the remissions of a remittent fever; in consequence of loss of blood or powerful evacuations; in the course of defervescence when this is excessive, and sometimes in the death struggle." Treating of collapse, he observes that the temperature very seldom sinks below 91 4°. He defines "collapse temperatures" as those below 96·8° and classifies them thus: (*a*) deep fatal algide collapse below 92·3°; (*b*) algide collapse from 92 3° to 95°. In these

circumstances it is possible to save life, but the patient is in the greatest danger; (*c*) moderate collapse from 95° to 96 8°; this is in itself without danger. He quotes Fleury as having observed the temperature of a subject in a cold bath sink to 93 2°, or even to 84·2°. Later he says: "Although in certain cases of cholera temperatures of 78·8°, or even lower, have been observed on the surface of the body we may be almost sure (from other observations in the same disease) that the rectal and vaginal temperatures were considerably higher." Again: "Löwenhardt [3] has published four cases of insanity in which lower temperatures occurred than in any hitherto observed. Before death, and indeed for several days, they showed 77°, 85·1°, 74·7°, and 82 4° They were very old people who got out of bed in the coldest time of the year, and ran about naked, and from their dirty habits were constantly being bathed, and who took hardly any food; in one case the pulse was only 45, and in another only 23 per minute." He quotes Magnan as giving a vaginal temperature of 78·8° in a drunken woman who lay out exposed to sleet all night. The temperature became normal in two days. Wunderlich states[14] that the lowest temperature which he had seen followed by recovery was 92·3° (the pulse beating 62 times in the minute). This was an instance of "collapse of defervescence" in enteric. Again, referring to cholera,[15] he observes: "The cutaneous temperature even in the axilla during the algide stage is, as a rule, diminished, sometimes, indeed, very greatly so, yet not often below 95°. The temperature under the tongue may be still more diminished. In the stage of asphyxia the temperature there seldom exceeds 87 8°, and even in cases which recover may fall to about 78 8°. If it fall below this recovery would appear to be impossible." A little further on[16] he quotes two cases, reported by Fischer, of injury to the cervical cord in which temperatures of 93·2° (rectum) and 86·3° (axilla) were recorded; and likewise a case (Wagstaffe) of fracture with dislocation of the sixth cervical vertebra where a temperature of 92 3° was recorded on admission which sank to 81·7° in the ensuing 45 hours, the patient dying three hours later. Later still,[17] he refers to the influence of inanition, especially when aggravated by exposure, loss of blood, vomiting, diarrhœa, exposure to cold, &c. Just before death the temperature may be very low, especially in the syphilitic marasmus of children, of which he gives an instance with a temperature of 77° in the rectum. He also notes a case of ordinary marasmus in which the temperature was 83 4°, and declares on Roger's authority[18] that the axillary temperature is very low in congenital induration of the areolar tissue (sclerema) of new-born children. Roger found that in 29 such cases the average temperature was 87 8°, and of these in seven cases it marked less that 78 8°

Greenhow [19] has reported an axillary temperature of 84°, but the nature of the case is not stated, and included in the charts at the end of Wunderlich's remarkable monograph are three examples of subnormal temperatures—Fig. 10, temperature 92·3°, typhoid with collapse (this patient apparently recovered); and Figs. 75 and 76, temperatures 95° and 95·1° (both these patients died from acute miliary tuberculosis).

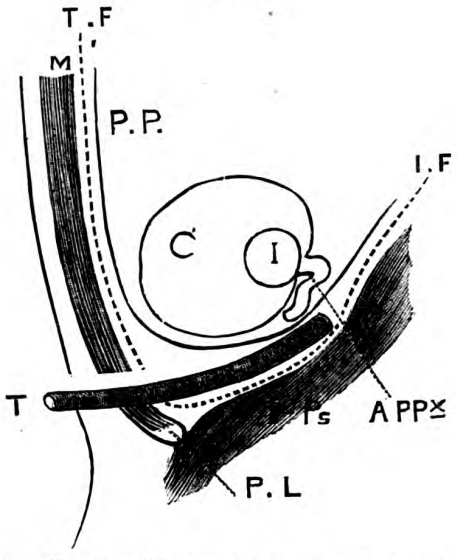
A MODE OF OPERATING IN CASES OF APPENDICITIS,

ADAPTED FOR USE ON ANY DAY OR AT ANY STAGE OF AN ACUTE OR SUBACUTE ATTACK, THOUGH NOT INDICATED IN EVERY CASE.



BY C. B. KEETLEY, F.R.C.S. ENG.,
SURGEON TO THE WEST LONDON HOSPITAL.

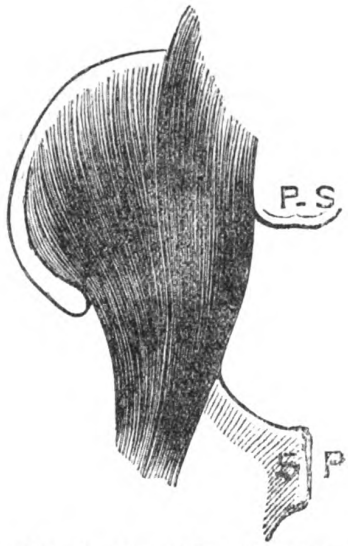
WITH reference to Mr. C. Mansell Moullin's interesting paper, "Early *v.* Late Operation in Cases of Inflamed Appendix," which appeared in THE LANCET of Dec. 16th, 1899 (p. 1657), and to Mr. James Berry's valuable letter on the same subject in THE LANCET of Dec. 30th (p. 1857), I would call attention to the circumstance that both these gentlemen when writing of "early operation" for appendicitis evidently mean one which opens the general peritoneal cavity and removes the appendix. I wish to describe another mode of early operation which has, I believe, certain advantages.

I would say previously that to some extent I share Mr. Berry's belief that early operations for the removal of the appendix are occasionally performed which result in the loss of life which patience might have saved. But the cases of this kind which have come under my observation have never been *very* early operations. None had been operated on in the first 36 hours. Such a rule as that of waiting until the fifth day I should strongly object to. I believe that more cases operated on from the fifth day to the tenth day are fatal than any others. But that may be because many physicians who do not call in the surgeon till the fifth day would not call him in at all if the symptoms were less serious than those of general peritonitis or acute intestinal obstruction. Therefore I feel, and always have felt, the force of what is really the point of Mr. Moullin's paper—viz., Are we still to fold our hands and leave to chance so many cases the course of which we cannot foresee with certainty? When Mr. Berry writes that, "provided that the patient be kept *absolutely at rest* in bed and not disturbed by purgatives or enemata or other injudicious treatment" diffuse peritonitis rarely supervenes, he is probably right. An exceedingly able and practical physician used to make this view the basis of a firm opposition to *all* surgical intervention of any kind and at any time. A few years ago he suddenly veered to the other extreme, driven thither, I suspect, by a run of ill-luck. Delirium, obstinacy, disobedience, the feeling that "a good motion would relieve all the symptoms," fussy relatives, careless nursing, have all been known to disturb the perfect rest, &c., prescribed for these cases. Another danger is that of heavy-handed palpation of a small collection of pus or of a recent extravasation. Tenderness generally prompts the patient to protect himself from this, but when he is well dosed with opium that protection may be lost. The argument in favour of early intervention is not dependent on statistics, which, as Mr. Berry himself shows, may be easily manipulated. Still less does it rest on Mr. Moullin's personal statistics, whatever they may be.

The mode of operating which I believe to be at all times safe, whether on the first or last day of an acute, a subacute,

FIG. 1.

Rough diagram to illustrate the operation. T. F., Transversalis fascia. M., Muscular and aponeurotic layers of abdominal wall. P P., Parietal peritoneum. C., Cæcum. I, Ilium I. F., Iliac fascia. APPx, Appendix vermiformis. I-Ps., Ilio-psoas muscle. P. L., Poupart's ligament. T, Drainage-tube.



or a chronic attack (I do not say that it is at all times and in all cases indicated) may be described as follows. It takes into consideration the path by which the pus, when pus forms, usually mounts to the inguinal region of the

abdominal wall and it goes to meet it. At the same time it keeps as often as possible outside the peritoneal cavity.

The surgeon proceeds somewhat as if he wished to tie, extra-peritoneally, the common iliac artery. 1. The skin is incised above the anterior superior iliac spine and the outer half of Poupart's ligament, in a line parallel to the latter. 2. The external oblique aponeurosis is divided to the extent of the skin incision. 3. The deeper muscles are penetrated as much as possible by separation of their fibres and towards the outer part of the skin incision by cutting with scissors. 4. The transversalis fascia is divided. Hæmostasis is effected by the way customary with the surgeon operating. 5. The peritoneum is carefully separated from the iliac fascia, the surgeon at the same time palpating for the *deep surface* of the appendix or for the inflammatory thickening around it. 6. A strong light is thrown into the depths of the wound and signs of inflammatory infiltration of the tissues such as indicate the neighbourhood of pus are looked for. 7. If pus is found the infiltrated tissues are carefully torn open with two pairs of dissecting forceps, not cut or roughly punctured. 8. Whether pus is found or not two drainage-tubes of medium calibre are carried to the bottom of the wound. If a collection of pus is swabbed out the greatest gentleness should be employed. It is better not to use the douche or syringe.

Some critical person may say, "Why this is the ordinary mode of opening an abscess secondary to appendicitis." He will be mistaken. In the common operation for opening such an abscess, step 5 of my operation, which is all-important, has sometimes been performed roughly by the pus which has come to meet the surgeon. In my operation step 5 is performed by the surgeon who is going to meet the pus or, at least, to search for the appendix, and not waiting for some fifth, sixth, or other particular day when it may be the good pleasure of the pus to come to him, unless it should in the meantime prefer to spread with a burst all over the peritoneal cavity or elsewhere.

FIG. 2.

P. S., Promontory of sacrum. S. P., Symphysis pubis. A, Iliacus. C and B are on the psoas. The triangular area A B C indicates roughly the place in which the peritoneum is raised from the iliac fascia.

If in separating the peritoneum from the iliac fascia the former should be accidentally torn, use the opening for the purpose of an exploratory laparotomy, then close it with a suture and protect it with a thin fold of iodoform gauze wrung out in a solution (1 in 2000) of warm sublimate and continue the operation. If the appendix does not occupy its usual position behind and beneath the cæcum, or if the cæcum itself is abnormally placed, I need not say that indications of this may often be found before the skin is cut at all. If the cæcum and appendix are high up towards the iliac crest the parietal incision may be extended upwards, and, finally, a lumbar incision made for the drains (or one of them) which may still, with care, be kept extra-peritoneal. If the appendix is unusually near to, or even internal to, the brim of the pelvis it may be possible to reach it by directing the deep dissection rather inwards towards the pelvic brim. If the appendix, in spite of inflammatory thickening, floats free in the peritoneal cavity and the latter shows no sign of infection, I see no reason why the appendix should not be excised, whatever the day be, the first, second, or any other. If it is the centre of adhesions, possibly bounding pus, and the thickened mass floats comparatively free in the abdominal cavity then (1) if it can be done without tension, bring the inflamed mass and fix it by sutures through healthy tissues to some part of the parietal wound and leave that part of the wound open; (2) if the above course cannot be followed without dragging on the bowel either carry a drain down to the inflammatory mass or leave it alone altogether. Do not tear open the adhesions and remove the appendix if the patient is at the time in the throes of an acute or subacute attack, but wait till the temperature is normal or nearly so, watching the patient narrowly, giving him no opium, and re-opening the abdomen at once should signs of extension of the mischief appear.

There are two facts bearing on the above recommendations to which I would call attention. One of these is the remarkable tendency which pus and even fæces have to find their way out of an opening in the anterior abdominal wall if they have a chance of access to it, and in apparent opposition to gravity. I used to think, till experience taught me the contrary, that such infectious and polluting materials preferred to gravitate into the pelvis. Perhaps they would do this, but the pelvis is already fully occupied with intestines and other organs which behave as if they had a prior right there and resist displacement. Their resistance is, of course, overcome when there is intra-peritoneal fluid which cannot find a way out through some recently made parietal wound. The second fact is the impunity with which a limited part of the peritoneum may come into contact with septic fluid, provided that the latter is speedily and completely wiped off with sublimate swabs or carbolised sponges. Somewhat allied to this is the safety with which intestine may roll into the cavity of a pelvic abscess a few minutes only after that cavity has been thoroughly scraped, swabbed, and cleansed. No sensible person, of course, would leave them there, but I have been obliged more than once to leave intestine to form part of the wall of an abscess cavity so treated, because the abscess wall itself, when radically dealt with, no longer sufficed to shut off the general peritoneal cavity. No harm resulted, except once a temporary fæcal fistula leading into the small intestine. In this case a rectal fistula opened into the abscess cavity before operation and made permanent purification of it impossible.

In the last few years I have frequently operated on the principles above enunciated. A striking example of their application was the case of a middle-aged sergeant of police in the West London. His condition was at the time alarming; he had a distended abdomen, sickness, frequent pulse and respiration, and a temperature of 104° F. I reached the deep surface of the thickened mass around the appendix but found no pus. However, the tip of the palpating finger smelt distinctly of putridity. Drainage-tubes were passed in and the temperature fell at once, within 48 hours pus flowed, and within a fortnight a fæcal concretion came away. Ultimately I removed the appendix, more because it was necessary for him to return to duty within a certain time than for any other reason. This case impressed me because of its striking resemblance to cases in which I had seen intra-peritoneal operation with removal of the appendix during an acute attack result fatally. Nevertheless, had my patient been the subject of general septic peritonitis at the time the simple operation above described would not have saved him. The general peritoneal cavity itself would have had to be dealt with through a median incision and with counter openings.

I wish to add that I have had no experience of operating by any method on acute cases of appendicitis within 36 hours of the onset. I envy alike Mr. Mansell Moullin and Mr. Berry the possession of medical friends progressive enough to give the former the opportunity of operating on these early cases and the latter that of letting them alone

Grosvenor-street, W.

PRESCRIBING ALCOHOL *versus* OUR OWN INTERESTS.

BY FREDERIC C. COLEY, M.D. DURH.

WHERE well-to-do patients are concerned it is often our duty to recommend entire and permanent abstinence from all stimulants when regard to our own interests would suggest a prescription more in accordance with the patient's tastes and prejudices. But when we have to do with the working classes we shall be very short-sighted if we do not perceive that duty and self-interest more commonly point in the same direction. Let it not be assumed that in what I am stating I suppose a low state of morality in the medical profession. I am merely calling attention to facts which indicate that what is to the advantage of the community in general tends also to the profit of the medical profession in particular.

We have heard much of late about the abuse of hospitals by people resorting to them who are well able to pay for medical treatment. Now the practical question is not, how much does a man earn, but how much has he available for such purposes as paying for medical treatment for himself and family whenever that happens to be required? A lurid light is thrown on this question by the very carefully elaborated statistics of Mr. Rowntree which show that working-class families spend on an average 6*s*. a week on alcoholic liquors. If we could take out of the reckoning the many thousands of teetotal families who spend from choice nothing on alcohol and the very poor who from necessity spend very little the average expenditure of those families who indulge freely in alcohol would of course be found to be much more than 6*s*. a week. Nor is this all. Many employers of labour complain that large numbers of men who make good wages do not make nearly so much as they might, simply because they devote two or three days a week to idle drinking.

Now it is no doubt true that some people who have the money to pay for medical treatment prefer to apply to a hospital from mere stinginess. But it is more to the purpose that working people who waste more than 6*s*. a week per family cannot do otherwise than depend upon charity for medical treatment when they require it. So that although a radical change in the habits of these families in regard to drink would not *necessarily* improve their relations with the medical profession it is impossible for that desirable result to be brought about without it. It follows, therefore, that it is to the interest of the rank and file of the medical profession to encourage the practice of total abstinence with all their might. I am not going to suggest that we should all straightway "sign the pledge" and become members of the British Medical Temperance Association—though we might take more suicidal steps than either of these. But this we can easily do: make it a settled rule of our practice never to prescribe alcohol unless we are convinced that no safer remedy will produce the desired effect, and never to prescribe it at all for trivial ailments. Whenever we believe that alcohol is necessary and no other remedy will serve as well, then it is prudent to avoid the ordinary commercial forms of alcohol and prescribe rectified spirit, to be dispensed in a medicine bottle and flavoured as may seem desirable. In this way only can we secure scientific accuracy in the strength and dose of the stimulant and we materially lessen the danger of the use of the drug being continued after the need for it has ceased. And we should never forget one very strong argument in favour of the course which I am recommending—viz., that the mere presence in the house of any of the ordinary forms of alcohol may be a dangerous temptation to other members of the household beside the patients for whom it was prescribed.

But we need not, and ought not, to be content with merely avoiding the prescription of alcohol except in extreme conditions and even then taking special precautions lest our prescription might do harm directly or indirectly. We should take every possible opportunity of using our whole influence to enforce the conviction that the habitual use of alcohol is not only unnecessary but positively unfavourable to health and long life. The statistics of life insurance companies and friendly societies will furnish us with ample justification for taking this position.

It does not admit of doubt that if the whole of the medical profession would act upon the principles just suggested before long some millions of pounds would be diverted from the liquor trade to more desirable channels, and the result would be a great gain to all concerned except the liquor traders. And even they would lose very much less than the community as a whole would gain. For the enormous indirect loss from alcoholism by the ways of sickness, and idleness, and imprisonment, and general inefficiency, brings no gain to anybody. Until this stupendous waste of money and the power to earn money is greatly diminished a very large part of the working classes must be more or less dependent upon charity in times of sickness. And medical charity is the kind which is most readily sought by people who would not think of asking for charity in any other form. Hence the problem of the inadequate remuneration of the medical profession and the drink problem are very closely related.

But there is a more altruistic aspect of the drink problem which should appeal with especial force to medical men. The prevention of phthisis and other forms of tuberculosis is a matter in which we are all most keenly interested. Overcrowded, ill-ventilated, dark, and dirty tenements are just the places where the tubercle bacillus finds its victims and spreads readily from one to another. And they, going out and scattering their infective expectoration in railway carriages, &c., become dangerous to others whose homes are too airy and cleanly to give the bacillus much chance to live outside of the human body. The prevention of tuberculosis is hence mainly a question of improved dwellings for the people. In London the housing of the working classes is a problem beset with special difficulties. But in most other places it is simply a question of £ *s*. *d*. It hardly needs pointing out that less than 6*s*. a week (the average amount shown to be wasted on drink by the families of the working classes) is needed to make the difference between the rent of two crowded rooms in a filthy, unhygienic tenement house and the rent of a decent home in a fairly wholesome neighbourhood. It follows that nothing is likely to have such a decided influence in the prevention of tuberculosis as the general adoption of the practice of total abstinence from alcohol.

The majority of the medical profession know the ways of working men well enough to be quite aware, from their own observation, that a working man who does not abstain from alcohol altogether commonly spends much more upon it than he can well afford, even though he may not deserve to be called a drunkard. We ourselves may be fortunate enough to possess an income which places us above the necessity for close consideration of economy, and we may believe ourselves indued with such self-control that we feel no fear that we shall be tempted to excess. But we ought not to forget that our working-class patients are very differently circumstanced: they cannot afford to waste money and it would be hard to find a poorer investment for their wages than spending them in drink. There is nothing more likely to draw a working man away from the practice of total abstinence than "doctor's orders" thoughtlessly given.

I shall make no apology for attempting to show that in taking the course which is manifestly to the advantage of the whole community we are also likely to benefit ourselves. The man who fails to do his duty because his interest is opposed to it is a rascal. But the best of men may find it easier to do his duty when he knows that material advantage to himself is likely to follow.

Of course, all this is dead against Dr. Reid's theories about alcohol and heredity. According to him the way to secure sobriety for the human race some thousands of years hence is to let alcohol have its own way for the present, and (with the aid of those beneficent eliminators of the unfit, poverty, and starvation, and tuberculosis, and crime) get rid of all who have "an inborn capacity for delighting in it." I do not suppose that most of my readers will feel that the necessary sacrifice of this delightful dream of the future is a fatal objection to my suggestions for present action. Some of us may venture to doubt whether Weissmann's facts are sufficient to support his own theory. But the inverted pyramid of inference which Dr. Reid has tried to balance upon Weissmann's dogma would topple over even if the foundation upon which he has rested it were firm as rock.

Newcastle-on-Tyne.

DIET IN TYPHOID FEVER.

BY R. W. MARSDEN, M.D., D.P.H. VICT., M.R.C.P. LOND.
MEDICAL SUPERINTENDENT, MONSALL FEVER HOSPITAL.

THE plea for a less restricted diet in typhoid fever which was advanced by Dr. A. G. Barrs in the *British Medical Journal* for Jan. 16th, 1897, does not seem to have evoked that response to which it is probably entitled. Feeling with him that it is advisable to alter our rules in this respect, I have ventured to record the results obtained in 200 unselected cases of typhoid fever. Perhaps the word "unselected" is hardly quite correct, for, in order to be sure of the exact stage of the disease at which the various changes in diet were made I excluded all cases which had not been admitted during the acute febrile period. By this means also, the diagnosis has been verified clinically, and the possibility that the positive serum reaction was due to a recent attack of the disease has been negatived.

Before considering these cases it is interesting to inquire what has been the origin of the present accepted method of diet in typhoid fever. The history of medicine shows only too well how the profession as a whole can proceed along the wrong path, and I venture to affirm that with regard to this disease the method of diet is still in the stage of evolution and that simple and stereotyped as the present teaching is it will yet give way to a more rational and less restricted system. Until well into the present century fever, looked upon as an entity, was regarded as due to general or topical inflammation and its treatment consisted in a rigorous system of depletion, one of the factors in the depletion being low diet or even total abstinence from food. The first advance was made by Dr. Graves,[1] who wrote: "I am convinced that the starving system has in many instances been carried to a dangerous excess and that many persons have fallen victims to prolonged abstinence in fever." Though proud of his innovation he further says that one must not fall into the opposite extreme of overloading the stomach, as under such circumstances "gastro-enteric irritation, tympanitis, inflammation and exasperated febrile action are the consequences." Not believing in the separate entity of typhoid fever no specific rules are obtained from Dr. Graves's teaching, but for fever in general it is found that he allowed well-boiled gruel, toasted bread, and then animal jelly or broth. He makes no mention, however, of the time for giving solid food, though he records instances where "an incautious indulgence in the use of animal food was followed by a fatal result," and where the partaking of beefsteak at an early period of convalescence from fever was followed almost immediately by a relapse and death from enteritis in 36 hours. A little later Trousseau[2] accepting Graves as his guide, gave definite rules for dieting this disease, and apparently instituted the present method, for, after inveighing against the previous system of starving, he says: "Care must be taken not to fall into the opposite extreme of those who are not afraid to give solid food at the beginning and during the course of continued fevers." He even says that it must be given "always in small quantity and in the liquid form," and insists, at the decline of the fever, on "the necessity of restricting the patients to light farinaceous food," giving as his reasons for this teaching the statement that the medical attendant thus avoids "bringing on attacks of indigestion, which, though they may not cause serious gastro-intestinal mischief or (as sometimes happens) fatal peritonitis, may nevertheless lead to relapse or may retard restoration to health." The first time-limit was apparently given by Murchison[3] who, though he allowed "milk, eggs, broths, jellies, bread and milk, custard, sago, &c.," during the acute stage, yet specified that during convalescence "notwithstanding the cravings of the patient's appetite, the diet must be restricted to such articles as milk, eggs, farinacea, custards, light puddings, &c. Meat ought not to be allowed for at least seven days after the cessation of pyrexia and before meat is given it is well to try for a day or two a piece of boiled sole, smelt, or whiting. It is perhaps well to observe in passing (1) that the above diet for the acute stage is more liberal than that which is usually allowed; (2) that it is too liberal for the severest cases, in which the patients can only be fed by pure fluids; and (3) that in a case of any severity, even by the graduated system which I have adopted, seven days may be too short a period in which to receive meat other than minced. The exact rules followed at present, and which it is unnecessary to mention, seem to have been evolved shortly after the appearance of Dr. Murchison's work. They are given in detail by Dr. Fagge[4] and apparently repeated by subsequent writers.

It would thus seem, as Dr. Barrs has pointed out, that there are no exact observations to show that "solid food *per se* is bad and liquid food *per se* is good in febrile states," and though we are told that during fever the secretion of saliva and of gastric juice is diminished, yet illustrations as to the ability such patients show for digesting food make one agree with Stokes[5] that "no matter what Beaumont might say about the stomach not digesting when the patient had fever, in thousands of cases patients in fever digested remarkably well, required food, and derived benefit from it." Dr. Stokes gives an amusing incident where a lady caused much excitement amongst her medical attendants by partaking of salt beef and cabbage though in a febrile state, and concludes that "there can be little doubt that in many cases of advanced fever a greater latitude in the use of food might be adopted with advantage." The continuance of such a "restricted diet" in typhoid fever must therefore stand or fall upon the verification or refutation of the statements made since the time of Trousseau, that too early a recourse to solid food is likely to entail harmful consequences, for, if this were true, then all would admit that "it is absolutely necessary to resist their demands for food, when, as is usually the case, they have a craving appetite."

Before proceeding further, I think it advisable to give an idea of the method upon which these 200 patients were dieted. It will thus be possible to dispel the idea that by solid food is meant a liberal supply of beefsteak, &c., and it will further allow one to form an estimate theoretically of the chances of harm accruing from the changes proposed. In the first place, I wish to express myself as upholding the necessity for the retention of definite rules in the dieting of typhoid fever. As a matter of fact, the dietary for these 200 patients has been almost identical with that usually allowed, though it has been much altered in its application. Thus all patients have received milk only at first and have passed through the usual stages with greater or less rapidity according to their condition. The patient in a mild case without contra-indication would receive on successive days bread-and-milk with custard, fish with mashed potato, chicken, bread-and-butter, and, finally, minced meat, remaining at this stage until convalescence was well established; whereas in a severe case peptonised milk alone or with meat juice, &c., might have to be continued well into the "period of convalescence." Speaking broadly, the individual patient and his condition have been alone considered and slight exacerbations of temperature or occasional irregularities of the bowels have not *per se* caused the withdrawal of the food when no evidence existed of a distinct causal connexion. Practically I agree with Dr. Barrs that the patient's wishes constitute a most important help, and would add that his actions are an almost infallible guide. For a patient in the so-called "typhoid state" to ask for food is incredible, but even short of this condition so long as the tongue is dry no one would think of complying with a request for solid food if it were made. On the other hand, if a patient says that he is hungry or expresses a wish for an addition to his food and an examination reveals no reason to doubt the genuineness of his feelings a beginning would be made, though the exhibition of any whim or of early satiety and disinclination to eat with avidity that which was allowed (be it bread-and-milk or minced meat) would be taken as an indication that the request had been premature, and under such circumstances no increase in the diet would take place. It should be distinctly understood that on no occasion has solid food been forced upon a patient. As a rule, if they have not been the *vis a tergo*, they have at any rate accepted cheerfully what has been given, and never since the adoption of this system have I experienced the groaning and grumbling which used to be so marked a feature during early convalescence when their legitimate cravings were resisted. Taking now the evidence of my own 200 cases an

examination of them shows that in 100 cases fish[6] was allowed prior to the termination of defervescence; in 36 cases it was given on the day on which defervescence might be said to be complete, even though the temperature was not settled; whilst in 64 cases it was given subsequent to the completion of the defervescence. If, however, one takes the day on which, the evening temperature being normal, a period of 24 hours' normal temperature followed, then in 151 cases fish was given before that day, in 16 cases coincidently with it, and in 33 cases subsequently to it—viz., in 12 cases one day after, in three cases two days after, in 10 cases three days after, in five cases four days after, in two cases five days after, and in one case eight days after.

What evidence is there that evil effects have followed the change? The various injurious consequences of a too early administration of solid food which have been advanced are (1) diarrhœa, (2) hæmorrhage, (3) perforation, (4) pyrexia, and (5) relapse.

1. *Diarrhœa.*—If the etiology of diarrhœa is considered we find that it is probably proportionate to the severity of the attack (Louis), that it has not a necessary relation to the extent of the intestinal lesions (Fagge), that it is worse when the colon is ulcerated (Addison), and that it is due chiefly to the associated catarrh (Osler). Of these various factors the last only can be conceived as being capable of being affected by diet, and one would not expect to obtain other evidence of its production than the occurrence of vomiting, unusual abdominal fulness or uneasiness, or increased action of the bowels. Vomiting and increased abdominal discomfort have been marked only by their total absence, whilst, as regards diarrhœa, in 61 cases it was absent throughout; in 29 cases, though it was present at the time fish was given, there was no interference with its steady improvement; and in 107 cases in which it was present at some period of the attack, though not at the time when fish was given, there was not the slightest evidence of its recrudescence. There remain three cases only. In one of these cases an attack of diarrhœa had apparently just ceased when, fish being given, a return of loose motions occurred; in the second case increased action of the bowels seemed to follow and steadily get worse, but after a few days it became evident that one was dealing with a relapse; and in the third case the patient was at the time at the height of a moderately severe attack of the disease. The known variability of the symptoms, I think, allows of the conclusion that in these three instances the apparent connexion was a pure coincidence and it can therefore be said that careful dieting with solids at an early stage does not produce diarrhœa or give evidence of acting as an irritant to the intestinal mucous membrane.

2. *Hæmorrhage.*—This is more common in the severe cases, especially when there is much diarrhœa, and is due either to the separation of the sloughs or the presence of fungating sloughs, or to the associated hyperæmia. Its greater frequency, if there is a general tendency to hæmorrhage, or when there is a family predisposition to this particular complication, or, again, its relation to age, need not concern us. By direct irritation only could one imagine food to assist in the production or aggravation of the above factors, but this has already been shown not to have occurred. This conclusion is supported by an examination of the cases for hæmorrhage, since of the six patients in whom it was noted in four it occurred before any solid food had been given, whilst the other two had been taking solids from shortly after admission, yet hæmorrhage did not occur until the end of the third and fourth weeks and was, moreover, slight in each instance. It will be noted that the percentage of hæmorrhage—viz., 3 per cent.—is somewhat low and that in none of the cases was it fatal. This is what would be expected when it is remembered that the most copious hæmorrhages are met with chiefly in the worst attacks with much diarrhœa, and that in these cases an advance to solid food is not likely to have occurred.

3. *Perforation.*—The same considerations apply also to perforation, the one complication probably which has more than any other been responsible for the continuance of the present *régime*. In this series of 200 cases there is not a single case of perforation, yet this complication has been more than usually prevalent during the period of their collection. This one fact, that in not a single instance where perforation occurred had an advance to solid food been made, would tend to make one doubt the statement that "there is certainly no relationship between this accident and the severity of the disease."[7] Of the different etiological factors "the taking of indigestible food" may be dismissed at once from a consideration of the dietary I have mentioned, whilst of the other factors—meteorism, vomiting, and most important of all a direct extension of the necrotic process through the whole thickness of the intestinal wall—it is impossible to conceive of any connexion except by directly acting as an irritant, for I have already stated that on no occasion has there been the slightest evidence of abdominal fulness or of vomiting as a result of the alteration in the diet.

4. *Pyrexia.*—Perhaps the mildest accident which can happen, but the one which is supposed to occur most frequently, is the production of an exacerbation of pyrexia, the so-called febris carnis. Now in typhoid fever it is well recognised that the most surprising variations in temperature may occur, apparently without cause, in patients who have been kept on milk, and I would therefore submit that the exacerbation of temperature so often described as occurring shortly after the giving of solid food is probably in most instances a pure coincidence unless the change has been made too suddenly, and further that if the exacerbation is only temporary and unaccompanied by other symptoms one is not therefore justified in continuing the practice of starvation. I use the term "starvation" advisedly for, like Dr. Barrs, I was compelled to give solid food in the first instance to a patient whose temperature would not settle and who, despite the most liberal use of nourishing liquids—beef essences, eggs, &c.—continued to sink until in desperation I ordered solid food and this was followed by a speedy and steady improvement. Now, considering the 200 cases, in 180 cases there was not the faintest evidence of any alteration in the temperature, in 11 cases a temporary exacerbation occurred after, in two cases there was the appearance of an increase in the morning and evening oscillations, whilst the remaining seven cases were connected with relapses which I shall next consider. Such a record cannot, I think, be in favour of the prolonged continuation of fluid diet in all cases.

5. *Relapse.*—Relapse or recrudescence occurred in 48 of the 200 cases. Of these in 12 instances it was "intercurrent," in nine it was "spurious," and in the remaining 27 it was "true." As the percentage for relapse has been variously estimated from three to 18 the above number, giving 13 5 per cent., is by no means excessive. A more important consideration is the relationship which the occurrence of the relapse bears to the giving of solid food. In considering relapses I have included the "intercurrent" and the "true" and have discarded the "spurious," all of which were probably due to complications such as constipation, &c. Taking, then, the 12 "intercurrent" cases in 11 of them the relapse occurred before the food had been changed, and six of these were followed by a "true" relapse beginning at periods of six days, 10 days, 13 days, or more after the giving of solid food. In the remaining case the relapse was apparently coincident with the giving of fish. Of the 27 cases of "true" relapse the onset took place at periods varying from 0 to 20 days after the day on which solid food had been commenced. The relative numbers and days are shown by the following list. In three[8] cases the onset occurred on the same day, in one case it occurred one day after, in one case two days after, in two cases four days after, in two cases six days after, in three cases eight days after, and in 15 cases from nine to 20 days after. With such variability it is obviously unfair to ascribe the occurrence to the food, and one must perforce conclude that the single "intercurrent" relapse, and the three "true" relapses, whose onset was apparently coincident with the giving of fish, did not own this as their causal connexion. It is of course generally agreed that a relapse must be due to a re-infection of the blood, and further "since, if the patient happens to die a few days later, the intestinal lesions are found to be so far advanced that they clearly must have begun before the obvious relapse set in,"[9] one is justified in concluding that there is less possibility of causal connexion

[6] Though I am personally of opinion that the articles of diet which I have previously mentioned are quite interchangeable and that a beginning could be made with any one, yet in my own cases the order which I have given was observed and I have therefore chosen the day for fish as the day on which solid food was begun, not considering that boiled bread-and-milk, custard, and farinaceous puddings could be included in this category.

[7] Osler: Principles and Practice of Medicine.

[8] All three cases occurred immediately on defervescence from primary attack.

[9] Fagge: Principles and Practice of Medicine.

when the relapse immediately follows than when its onset is delayed one or two weeks.

We are still ignorant of the factors concerned in the production of this re-infection, but I think some peculiarity in the individual patient or in the micro-organism will yet be shown to play a prominent part, since there seems to be a great tendency in families to one type of attack, and the prevalence of different complications, including relapses, seems to vary considerably in successive epidemics.

I think that from a review of these 200 cases it must be concluded that a careful system of dieting, such as I have mentioned, has no injurious consequences and when one considers the benefits obtained—viz., more rapid recovery, diminished risk of surreptitious feeding with possibly harmful substances, lessened tendency to bolt food when allowed without proper mastication, and, finally, lessened tendency to asthenic complications as post-typhoid anæmia, gangrene, &c.—one must admit they there is no justification for resisting a craving appetite in the manner at present in vogue.

Newton Heath, Manchester.

A SIMPLE AND TRUSTWORTHY METHOD FOR THE QUANTITATIVE ESTIMATION OF MERCURY IN URINE.

BY DR. SCHUMACHER (II.),

AND

W. L. JUNG, D.PH.,

AACHEN (AIX-LA-CHAPELLE).

IN 1895 A. Jolles in Vienna published a memoir[1] entitled "A Simple and Delicate Method of Qualitative and Quantitative Estimation of Mercury in Urine." In the introduction Jolles gives an account of the methods hitherto proposed and adopted and comes to the conclusion that none of them fulfil the conditions which are essential in a practically useful analytical method—namely, the combined properties of simplicity and speed in working, with trustworthiness and accuracy in the results. Jolles then details a method for which he makes the claim that it combines these advantages. He recommends the use of metallic gold (which he obtains in granular form by an ingenious process) so as to form an amalgam with the mercury, when the latter is precipitated by the addition of stannous chloride. The use of the granular gold Jolles holds to be a great advance on former methods in which zinc, brass, wool, copper wire gauze, &c., were used. It readily takes up the mercury when this is precipitated by stannous chloride, and is then present in finely divided particles and in the "nascent" state. The whole operation according to Jolles takes at most 20 minutes.[2] In order to test these statements we prepared granular gold strictly according to the directions given by Jolles and with it made experiments, by his method, on mercurial solutions of different strengths. It was evident, however, that in no instance did complete amalgamation take place. As soon as the stannous chloride was added to the solution of bichloride of mercury, which was heated to 70° or 80° C., a more or less distinct clouding occurred, or a greyish precipitate of metallic mercury. The mixture was thoroughly stirred, shaken, and gently heated for a long time in order to bring the gold and mercury as much as possible into intimate contact, but in the end it always remained turbid, an evidence that the mercury had not been fully taken up by the gold. The mixture was allowed to settle and we tried to amalgamate with the granular gold the grey to black-coloured mercury which had all settled on the bottom. This only took place partly. A comparatively large quantity of free mercury always remained over.

We therefore consider it certain that it is impossible to effect a complete amalgamation of small quantities of mercury with gold in fluid media. Firstly, it was evident that the grey to black turbidity did not depend upon combinations with the tin; moreover, we took care that there was an excess of hydrochloric acid always present both in the clear, filtered solution of stannous chloride and in the mercurial solution. In many trials, which we varied in every possible way by the use of gold in smaller or larger granules, in the finest spongy form, and finally in "leaf" form, we obtained no better result. After our experiments we therefore cannot agree with Jolles's conclusions. L. Böhn[3] recommended another method of quantitatively estimating mercury in the urine which Rud. Winternitz published[4] and improved upon.[5] Winternitz obtained good results with his method, but it is hardly practical, both on account of the technical details in carrying it out and also on account of the length of time, from three to four days, which it requires. As our object was the estimation of the amount of mercury in the urine of syphilitic patients we needed a method which would combine the accuracy of Winternitz's method with the practicability and rapidity of that of Jolles. We therefore thought that we should attain our purpose if we could suitably combine the two methods mentioned. We then tried to obtain a complete union of the two metals by bringing the metallic gold for as long a time and as thoroughly as possible in contact with the solution containing the precipitated mercury. With this object in view we made a U tube of hard (potash) glass and partly filled it with the granular spongy gold. On one limb of the tube a bulb was blown to prevent small particles of gold from being carried over mechanically with the fluid. With the like object we placed two little glass rods in both limbs of the tube. We poured in corrosive sublimate solutions of different strengths, mixed with hydrochloric acid and stannous chloride. We tried it both warm and cold and poured it in both quickly and quite slowly, and even drop by drop, but we always found that the fluid which came through was more or less clouded with fine particles of precipitated mercury.

We arranged some quantitative analyses as follows. We weighed the carefully dried tube before running in a solution containing a known weight of mercury. After the solution had been slowly passed through we washed out the tube with water, alcohol, and ether, then dried and again weighed it. The difference of weights gave the weight of the metallic mercury which the gold had taken up. It was then again evident that a complete amalgamation of the two metals never took place as the weighings showed a loss of from 30 to 50 per cent. This method, then, as well as that of Jolles seems only useful for qualitative and not for quantitative analyses.

It may be mentioned that we used yet another form of gold, the so-called "true gold leaf," instead of the spongy granular gold of Jolles for filling the tube, but with this also we obtained no better result. It yet remained to prove that the turbidity of the fluid which came over was really due to mercury. We allowed the fluid to settle, and brought the grey to black deposit into prolonged contact with some granular gold, and then poured off the liquid. The gold amalgam was washed with water, alcohol, and ether, and then dried and heated in a test-tube with a small piece of iodine. A reddish-yellow ring of mercuric iodide was formed. We finally succeeded better when we combined R. Winternitz's method of amalgamation with mechanical filtration in the following manner. We prepared a small tube thus: a piece of hard glass tubing (Jena potash glass), with walls that were not too thick, was drawn out at one end in the flame of the blowpipe into a narrower part, and in this portion a thorough mixture of asbestos and "true gold leaf" was placed. We chose true gold leaf so as to get the gold in the finest possible state of division. The mixture was made by rubbing together pure white asbestos and pure gold leaf, washing out with hot hydrochloric acid, hot water, alcohol, and ether, and drying. In the lower portion of the wide part of the tube immediately above the narrow part we put a thick plug of asbestos to prevent any fragments of gold getting through and over it the layer of the mixture. The tube was then connected with a suction bottle, which was in turn connected with a water exhaust-pump. After these preparations, followed by a further thorough washing out with hydrochloric acid, water, alcohol, and ether successively, the apparatus was dried by gently heating with a small Bunsen flame and aspirating a constant stream of air dried by passage through concentrated sulphuric acid. The tube was weighed and the following three experiments were made.

[1] Monatshefte für Chemie. Band xvi., 1885, pp. 684–692.
[2] Op. cit., p. 689.
[3] Zeitschrift für Physiologische Chemie, Band xv., pp. 1–36.
[4] Archiv für Experimentelle Pathologie und Pharmakologie, 1889.
[5] Archiv für Dermatologie und Syphilis, 1889, pp. 783–828.

In the first experiment a solution of corrosive sublimate containing six milligrammes of mercury was poured into about 200 cubic centimetres of a heated mixture of distilled water, stannous chloride, and hydrochloric acid, and after allowing it to stand a little the resulting cloudy fluid was aspirated through the filter-tube. The filtrate was clear and remained so after 12 hours, with the exception of some little shreds of asbestos, which had escaped. The tube was carefully washed with warm water, alcohol, and ether, and with hydrochloric acid to get rid of the tin. By means of a suction pump a stream of dry air was drawn through for some time, and by very gentle warming the tube freed from all moisture. The weighing gave 5·2 milligrammes mercury instead of the six milligrammes which had been passed through. On heating the tube to redness a deposit of mercury formed in the narrow neck, which gave the typical reaction with the vapour of iodine. In order to test whether we could get a good result by simple filtration through asbestos we made an experiment in every way similar to the foregoing, but without using gold. We obtained only 3·4 milligrammes of mercury from the six milligrammes passed through. The loss was evidently due to the long continued passage through the tube of a stream of air heated gently in order to dry it. Some pieces of asbestos that were black to start with became obviously lighter in colour: thus a partial volatilisation of the mercury took place. An explanation of the ready volatility of the mercury in this experiment is that here the mercury existed as a free metal instead of being present when gold was used in the amalgam which the latter forms at once, and which requires a greater degree of heat to become decomposed, consequently the mercury present in the free uncombined condition in the asbestos filter is more easily volatilised at a proportionately lower temperature than the mercury contained in the gold amalgam.

The second experiment was conducted in the same way as the first, except that five milligrammes of mercury in about 300 cubic centimetres of water, hydrochloric acid, and stannous chloride were used in order to have a dilute solution. We found 4·3 milligrammes of mercury as the result of the weighings. Here also the slight loss was accounted for by the fact that some little pieces of asbestos were carried through. We therefore altered our procedure in the following manner. Instead of weighing the tube twice, once before filtering the mercurial solution and once with the mercury, so as to weigh the mercury directly, we calculated it indirectly from the loss of weight of the tube after heating it to redness. The tube was weighed after passing the mercurial solution and drying as before. It was then heated to redness and again weighed.

In the third experiment four milligrammes of mercury were dissolved in 500 cubic centimetres, thus making a very dilute solution. The quantity found by this method was 3·7 milligrammes of mercury. From this experiment our method seemed practical, but nevertheless a slight loss occurred in our process which would be of importance in working with still smaller quantities of mercury.

In order to remedy this defect we endeavoured to obtain the gold in yet finer sub-division than we had in the mixture of asbestos and gold leaf and we discovered an excellent material for our purpose in the hitherto unknown "gold asbest," in which the gold is deposited in molecular subdivision on fibres of asbestos. To prepare this substance we dissolved chemically pure gold in aqua regia, and heated it to drive off the chlorine and oxide of nitrogen and until the solution of gold chloride contained only very little free acid. In this solution we placed clean, fine, fibres of asbestos and allowed them to drain after they had been soaked through with the somewhat concentrated solution of gold. Then they were dried in a porcelain dish on the sand bath. The dish was gradually heated over the flame, whilst from above a stream of hydrogen (which had been purified by being passed through permanganate of potash and liquor potassæ and dried with sulphuric acid) was introduced by means of a porcelain tube. After about 15 minutes the reduction of the gold chloride was complete and the asbestos appeared partly coated with finely divided particles of glistening gold. It was cleaned with diluted hydrochloric acid and then dried.

The preparation of "gold-asbest" by means of the double chloride of gold and ammonium which we tried, both with and without the use of hydrogen, is not to be recommended. We now used the "gold asbest" prepared after our method for filling our filter amalgam tube. We finally found that the most practical way was to put a thick pad of asbestos in the narrowest part of the tube, over this a layer of "gold asbest," then a layer of granular spongy gold, and finally a second layer of "gold asbest." Experiments gave the following results.

—	Experiment I.	Experiment II.	Experiment III.
Decimilligrammes of mercury in the form of corrosive sublimate in each litre of water	40	30	20
Decimilligrammes of mercury found	41	30	20

We afterwards worked with still more dilute solutions :—

—	Experiment I.	Experiment II.
Decimilligrammes of mercury added to each one and a half litre of water	20	20
Decimilligrammes of mercury found	21·5	20

These experiments show distinctly the usefulness of our method for quantitatively estimating mercury in very weak watery solutions of corrosive sublimate. They should be carried out in the following way.

The dilute mercury solution should be heated on the water bath to about 70° C., then mixed with about 50 cubic centimetres freshly prepared, clear stannous chloride solution. After the solution has cooled a little it is aspirated through the filter amalgam tube already described, which is then washed with moderately warm diluted hydrochloric acid and afterwards three or four times with warm water. Finally, the water is got rid of with alcohol and ether, and the tube, after a slight warming at about 40° C., is dried by drawing a stream of dry air through it. The mercury forms a grey ring varying in tint from light to dark in the "gold asbest" layer in the tube. After drawing the air through for a quarter of an hour the tube is perfectly dry and is then weighed. Afterwards it is again connected with the stream of dry air and heated to redness in the Bunsen flame. After a little heating a precipitate of metallic mercury forms in the narrow part of the tube. The tube is left in the dry air apparatus until cold and then again weighed. The difference between the two weights gives the weight of mercury which was present in the solution filtered.

After obtaining such accurate results with watery solutions of corrosive sublimate by our method we did not hesitate to apply it to urine. Two milligrammes of mercury in the form of corrosive sublimate were mixed with a litre of normal urine free from mercury and the whole was warmed on the inverted condenser with hydrochloric acid and chlorate of potash till steam was given off in order to destroy the organic substances. The somewhat cooled urine was passed through a folded filter and stannous chloride and hydrochloric acid were added to the clear filtrate. From this point the working was exactly as described above. It appeared, however, that some organic substances which had not been destroyed were thrown down with the mercury in the asbestos. On ignition empyreumatic smelling gases escaped and the loss on heating showed 6 4 milligrammes instead of two miligrammes. We had then to devise some means of getting rid of the organic substances which remained after the first treatment with chlorate of potash and hydrochloric acid. We succeeded by repeated thorough treatment with chlorate of potash and hydrochloric acid, by which, it is true, some loss often occurred on account of the copious frothing. At times an almost explosive compound of the chlorate of potash and the organic substance was formed on warming.

Two experiments in which care was taken that there was no loss gave the following results: (1) 40 decimilligrammes of mercury were added to one litre of normal urine, and 36 decimilligrammes of mercury were found; and (2) 20 decimilligrammes of mercury were added to one litre of normal urine and 19 decimilligrammes of mercury were found. We now made extensive experiments with urine containing mercury from syphilitic patients, and finally employed our method, after many technical alterations and improvements, in the following way. One litre of urine in a two-litre retort flask of potash

glass was placed on the water bath and from 15 to 20 grammes of chlorate of potash were added together with about 100 cubic centimetres of strong hydrochloric acid. The mixture was warmed until the development of the chlorine was made apparent by the mixture becoming lighter in colour. It is advisable to attach a short inverted condenser. By the action of the nascent chlorine the organic constituents are for the most part destroyed and the mercury which is presumed to be in combination with them is changed into bichloride of mercury. The retort was then taken from the water bath and allowed to stand for 12 hours in order that the chlorine might act on the organic substances for a sufficiently long time. Afterwards it was again gently warmed and about 100 cubic centimetres of clear stannous chloride solution (prepared by warming excess of tin in concentrated hydrochloric acid and filtering through a hard filter) were added. After cooling a little it was filtered through an asbestos filter by means of the exhaust-pump and slightly washed. The asbestos filter was prepared from pure shredded asbestos on a porcelain filter which was placed in a moderately sized ordinary glass funnel. What adhered to the sides of the funnel was washed down with slightly warmed water from the wash-bottle, otherwise it adhered very firmly. The deposit, which along with the organic substances containing the mercury, together with a little hydrate of potash and some water, was placed in a retort holding about 300 cubic centimetres, into which it was entirely transferred by washing the funnel with warm liquor potassæ. The retort was placed in the water bath, slightly warmed, and allowed to cool. The organic substance was thus brought into solution and the action of the chlorine later was more thorough and took place quite quietly. Then (*after the cooling*) some crystals of chlorate of potash and concentrated hydrochloric acid were added. The chlorine formed destroyed the remainder of the organic substances entirely, and the mercury was all brought into solution as chloride. The solution was then filtered, best with the suction-pump (through a small filter plate on which there was a round close-fitting filter-paper, washed with as little water as possible). Afterwards the warm solution was mixed with from 10 to 20 cubic centimetres of stannous chloride and filtered through a filter amalgam tube filled with "gold asbest" and finely divided granular gold. The smallest particles of mercury were retained by this. The filter tube was then washed with diluted hydrochloric acid and water and afterwards three times with alcohol, then three times with ether, well dried in the dry air stream by which it was warmed a little at the start, and weighed till the weight was constant. Then the mercury was volatilised, the air current being again passed through. It had to be heated strongly as the "gold asbest" was a very bad conductor of heat, and the heating had to go on till the gold amalgam was thoroughly decomposed and the mercury entirely driven off. The tube was then weighed again till the weight was constant. The weight of the mercury contained in the sample of urine was the difference between the two weights. Three test experiments made by this method gave the following results:—

—	Experiment I.	Experiment II.	Experiment III.
Mercury (decimilligrammes) added to each litre of normal mercury-free urine	25	44	0
Mercury (decimilligrammes) found in urine	28	37	5

A series of three experiments was then made with pathological urine, each litre of which on an average of many analyses contained 20 decimilligrammes of mercury.

—	Experiment I.	Experiment II.	Experiment III.
Decimilligrammes of mercury added per litre	30	40·5	67
Decimilligrammes of mercury already present	20	20	20
Totals	50	60·5	87
Decimilligrammes of mercury found	60	55	77

We think that these figures sufficiently prove the usefulness of our method with respect to accuracy, and it can be carried out in a proportionately quick and easy way when once one has the apparatus for its performance, so that, with sufficient practice, three or four analyses can be made in 24 hours. Our method is very well suited to carrying out an extensive series of experiments which we have undertaken on the amount of mercury eliminated in the urine of persons who were undergoing a course of inunctions.

In conclusion we can confidently state that the method in the case of urine containing at least one milligramme of mercury per litre, by proper and careful work, according to our directions, gives absolutely accurate results. The results, as shown in the figures supplied, in cases where the urine contained less than one milligramme per litre, are only approximate. Our method has the advantage over that of Winternitz of being considerably quicker and easier in carrying out, and over the method of Jolles of being more certain and accurate with almost the same readiness and facility in working. The presence of an iodide does not interfere with the results obtained.

PROTRACTED GESTATION.

BY JOHN PHILLIPS, M.B., C.M., L.R.C.P. EDIN.

THE question of the duration of pregnancy being of considerable interest, not only from a medico-legal point of view, but also from that of general practice, I venture to report what I believe to be an authentic case in which it was prolonged to much beyond the usual period.

My patient was a primipara and unmarried. Intercourse was declared to have taken place on one occasion only—Sept. 6th, 1898—the girl's age at that time being only 16 years and four months. Her menstrual periods had occurred at regular intervals and they usually lasted about a week. Her last period had occurred in August, 1898, and had entirely ceased by the 24th of that month, this being the first day on which she considered herself "well," and it was from this date that I calculated the probable duration of pregnancy. In consequence of her missing her next two periods in September and October her aunt with whom she lived took her on Oct. 24th to a medical man in London, to whom the girl confessed, when questioned, that she had had intercourse, and he expressed the opinion that she was most probably pregnant. This proved to be the case and in April of the present year she came under my observation, and I was asked to attend her in her confinement, which I calculated would take place somewhere about May 29th, this being the usual average period of 278 days from the cessation of her last menstrual period (August 24th, 1898), from which I reckoned. Instead, however, of the confinement occurring at the expected time she not only went through the whole of June without a single pain, but labour did not set in until July 13th, on which date the pains began at 6 P.M.—*323 days after the cessation of her last period and 310 days after the date of coitus*, the child being born on the following day at 4 30 P.M. There is not the slightest doubt that no menstrual period occurred subsequently to that in August, as in addition to the girl's own statement her aunt, who always looked after her linen and who consequently always knew when her niece was unwell, declares that there "was not a stain" subsequently to the August period. During the entire pregnancy the girl had excellent health and there were no pains of any description prior to the onset of labour, which was perfectly normal and the presentation the usual cephalic one. Unfortunately at the time I had no opportunity of having the child (a female) weighed as it was sent away to be nursed almost immediately after its birth (within three hours), but although well proportioned and of good size it did not seem at all unusually large.

The late Dr. Matthews Duncan in his book, "Fecundity, Fertility, Sterility, and Allied Topics" (p. 348), is inclined to disbelieve in any case of supposed protracted gestation unless the size and weight of the child are above the average, considering that increased growth must follow lengthened gestation, but this cannot be taken as proved and, as Dr. Playfair points out, even if it be admitted the fœtus may have been originally small, so that at the end of the protracted gestation it may be of no more than the average weight and

there is certainly no reason to believe that the fœtus must necessarily be large simply because it has been retained longer than usual in the uterus.

This case, then, which lasted 323 days after the cessation of menstruation, is thus a parallel to the four instances reported by Simpson in which, reckoning from the same period, gestation was prolonged to 319, 324, 332, and 336 days respectively, and other instances as curious may be found scattered through obstetric literature. The case, however, becomes more exceptional and interesting when we consider the prolonged interval which elapsed between the date of actual intercourse and the onset of labour—310 days. Of the 46 cases reported by Dr. Matthews Duncan, who probably devoted more consideration to this subject than any other writer has done, he calculates an average interval between what he calls insemination (intercourse) and parturition of 275 days and other authors give other estimates—from 271 to 276 days. The longest of the series of cases recorded by Dr. James Reid in which he reckoned from a single coitus was 293 days and this he believed to be the extreme limit. Leishman, however, mentions one in which the interval was 295 days and Hedrich has recorded the case of a primipara who was delivered on the three hundred and ninth day after intercourse, whilst of those cases in which the duration of gestation has been determined by the death or departure of the husband Sir James Simpson reports one lasting 313 days and Dr. Hewitt another lasting 308 days. In more recent times Mr. Woollett reports[1] the case of a girl, 16 years of age, in whom gestation lasted 315 days from the date of coitus. In this case, however, labour pains occurred on the two hundred and eightieth day but passed off again, and another observer—Dr. R. McBride—has reported another case in which there was an interval of 295 days between a single intercourse and the occurrence of labour. It will thus be seen that the case of 310 days which I report is somewhat exceptional, and cases like these are of considerable importance from a medico-legal point of view.

In cases of contested legitimacy the English law and also the American, leaves the subject of the duration of pregnancy an open question, each case being decided on its individual merits, but in France and also in Austria a possible limit of 300 days is allowed, and this is extended to 302 days in Prussia.

There are still many practitioners who disbelieve in cases of prolonged gestation simply because they have not met with them in their own practice. There can, however, be little doubt not only that they occur, but that they probably do so with more frequency than is generally supposed.

Southsea.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

POISONING BY CORROSIVE SUBLIMATE IN A PREGNANT WOMAN;

RECOVERY; DELIVERY OF TWINS AT TERM; POST-PARTUM HÆMORRHAGE.

BY M. D. EDER, M.R.C.S. ENG., L.R.C.P. LOND.

ON March 11th a primipara, over 30 years of age and six months pregnant, took by accident two grammes (30 grains) of corrosive sublimate in powder with a draught of water. I saw her some three hours later. There were great pain in the mouth, throat, and abdomen, persistent vomiting, and considerable collapse. The lips, mouth, tongue, and pharynx were much injured. The stomach-pump was not used, but large quantities of white of egg in water were given assiduously. A quarter of a grain of morphia was injected hypodermically and warmth was applied, and later hypodermic injections of ether were resorted to. The following day the vomiting had ceased, the fresh symptom being diarrhœa with bloody mucus. The same treatment was pursued and small quantities of milk and beef-tea were given at short intervals. As soon as the patient was out of danger antiseptic mouth-wash and gargles were used. In about a month the patient was able to take solid food. No œsophageal stricture had resulted.

On July 4th I received an urgent call to the same patient. She had been in labour since July 1st. There was general œdema of the legs, vulva, arms, and face so as to make her quite unrecognisable. I was told that she had been thus swollen for two months but had not sought medical aid. The waters had broken, but nobody knew when; the presentation was normal. With the aid of forceps a full-term male child was delivered. Abdominal palpation showed another child with normal presentation. After waiting half an hour, good labour pains having returned, I ruptured the membranes and in a few minutes a dead female child was born. The placenta came away almost immediately by itself. The uterus contracted well, the pulse remained bad, but I was obliged to leave for other work. Some two hours later I was recalled to find my patient in a critical condition from post-partum hæmorrhage, a furious hæmorrhage taking place when I arrived. The radial pulse was not to be felt. The hæmorrhage was controlled by bimanual compression of the uterus, or rather by the one hand inside the uterus. As soon as hot water was obtainable hot douches were given and $\frac{1}{100}$th of a grain of ergotinine citrate tabloid was administered hypodermically. The bleeding was controlled and a transfusion of some two quarts of saline solution was given. The patient rallied considerably after this and fortunately no further hæmorrhage occurred. Her condition was critical for some days, but eventually a good recovery was made. The œdema entirely disappeared before she was out of bed. My requests for a sample of the urine at the time and since then have not been complied with.

A CASE OF ENORMOUS NASAL AND POST-NASAL POLYPUS; PARALYSIS AND DEATH.

BY ATUL CHANDRA MUKHERJI, C.M.S.,
IN MEDICAL CHARGE, RAI DOORYA PROSAD GHOSE BAHADOOR' CHARITABLE DISPENSARY, SOLAGHUR (DACCA).

A MAHOMEDAN male, aged 20 years, was brought to me in May, 1896, with an enormous nasal polypus which, distending the upper part of the nose to such an extent as to produce amaurosis of the left eye (from pressure) and enlarging the nasal bridge to four inches in width when measured from eye to eye, passed down the left nostril and almost occluded his mouth—so much so that it was difficult to feed him even with a spoon. Finding all other measures fail I advised removal by operation at Dacca which he declined to submit to. I then suggested minor surgical intervention, but as the tumour was more or less cartilaginous and some portion of it might have intruded into the cranial cavity and implicated the anterior lobe of the brain I did not feel justified in operating, and the patient ultimately died, but a fortnight before he died complete paralysis, without coma or loss of intellect, supervened, and during the 11 days just preceding his demise he had incontinence of urine and fæces. No post-mortem examination was allowed.

BRISTOL DISPENSARY.—The annual report of the committee of this institution has just been issued and shows that during 1899 there were 10,835 patients treated who, with 1165 remaining at the end of 1898, made a total of 12,000. During 1898 there were 10,176 patients treated. The report adds that during the past year medical assistance has been given in 25 difficult midwifery cases and the three beds at the Bristol Convalescent Home are much appreciated by the patients.

NEW WORKHOUSE INFIRMARY AT LISKEARD.—At Liskeard on Dec. 30th, 1899, the new infirmary erected in connexion with the Liskeard Workhouse was formally opened by Mr. Preston Thomas, the Local Government Board Inspector. The building contains 60 "Lawson Tait" beds and has been erected at a cost of about £5500. Mr. Henry Chaplin, M.P., President of the Local Government Board, telegraphed "congratulating the guardians on the excellent work they have accomplished on behalf of the sick poor of their union."

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

KING'S COLLEGE HOSPITAL.

A CASE OF CHRONIC MIDDLE-EAR SUPPURATION WITH THROMBOSIS OF THE LATERAL SINUS IN WHICH THE INTERNAL JUGULAR VEIN WAS NOT LIGATURED; RECOVERY.

(Under the care of Mr. ARTHUR H. CHEATLE.)

THROMBOSIS of the lateral sinus occurring during the course of otitis media may have either of two pathological causes. On the one hand, it may be due to the passage of micro-organisms from the middle-ear through the wall of the sinus; thus a thrombus is formed, which contains the bacteria which have given rise to it; this clot readily breaks down, and therefore in these cases there is a very great probability of the occurrence of embolic pyæmia. On the other hand, the blood may clot in the lateral sinus, owing merely to a "spread of the inflammation" from the surrounding structures; in this case the coagulation is probably the effect of the transudation of toxins, and the clot so formed is firm and has little or no tendency to become disintegrated. It is not possible to distinguish clinically between these two conditions until some infective manifestation occurs, such as a pyæmic embolus; but a rigor is very suggestive and is quite sufficient to justify ligature of the internal jugular vein. A case somewhat similar to the one recorded below has been published by Röpke.[1]

A boy, aged 14 years, attended at King's College Hospital on June 26th, 1899, complaining of pain round the left ear and of vomiting. 18 months previously he had had a discharge from both ears which "was stopped." On two occasions since then he had suffered from ear-ache, but there had not been any discharge. Five days before being seen at the hospital he had pain in his head and commenced to vomit. The pain, which was at first intermittent, had become continuous. The vomiting had caused great distress, and as no food could be retained he had rapidly lost flesh. Two days before admission the ear had discharged with some relief to the pain. Giddiness had been complained of for two days. A marked shivering fit occurred during the night before the visit to the hospital. The boy looked wasted and anxious and was extremely restless. He was sensible and answered questions readily. On walking he had a tendency to walk towards the right. The tongue was white, furred, and moist. The temperature was 100·2° F. and the pulse was 104. An offensive brown discharge came from both ears, a perforation being present in Shrapnell's membrane on each side. There was no bulging of the posterior superior deep meatal wall in the left ear, nor did the auricle stand out, and there was no redness or swelling behind it. Marked tenderness on pressure was present behind the mastoid process and below the ear where glandular enlargement could be felt. The heart and lungs were normal. Mr. Cargill reported that papillitis was present in both discs equally.

A few hours after admission the patient was placed under chloroform. The antrum was found to be full of granulations and cholesteatomata. On laying the antrum into the middle-ear the malleus and incus were found, both carious. The attic and middle-ear were then thoroughly cleared. On examining the walls of the antrum a discoloured and softened patch of bone was found in the posterior, leading directly to the lateral sinus. The sinus having been exposed for over an inch of its length it could be seen that it was occupied by a firm clot which was dark in colour except at the point of infection, where it was slightly yellow and evidently breaking down. As giddiness had been a marked symptom the cerebellum both in front of and behind the sinus was thoroughly explored but with no result. The dura mater, which had been incised, having been stitched up with catgut the sinus was laid open for the whole of its exposed length and the clot was turned out. As the clot for some distance above and below the point of infection was dark-coloured and firm it was decided not to tie the internal jugular vein but to clear the thrombus out as far as possible from the wound. For this purpose a sharp spoon was first carefully passed downwards, no bleeding occurring. A gauze plug having been prepared the spoon was passed backwards towards the torcular; after some clot had been gently removed a free gush of blood took place, shooting out a healthy-looking mass of clot fully one and a half inches in length. The bleeding was easily controlled by the plug. The whole wound was then packed with iodoformed cyanide gauze. The operation occupied one and a quarter hours. An hour after the operation a rigor occurred, the temperature reaching 102·4°. From that time the progress was steady and uneventful but slow. On July 10th, as the hospital was closing, the patient was transferred to St. George's Hospital under the care of Mr. Marmaduke Sheild, who kindly looked after him until he was sufficiently well to be moved to the convalescent home.

Remarks by Mr. CHEATLE.—That ligation of the internal jugular vein is not always necessary in thrombosis of the lateral sinus is well recognised, but no guiding rule has been laid down. Young[2] has described a case in which recovery took place without ligature of the vein, and no doubt many surgeons have had the same experience. Bronner has related a case in which the clot as seen through the wall of the sinus looked healthy throughout, and it was therefore left unopened with a happy result. It seems that if healthy-looking clot can be seen well below the breaking-down area ligation of the vein is not necessary; but in order that such a condition may be found it must be well recognised that *one* rigor demands instant operation. A rigor does not necessarily mean that there is septic thrombosis of the sinus, for in a case under the care of Dr. Urban Pritchard in King's College Hospital a severe rigor occurred as a result of an acute empyema of the antrum, and no further bad symptom followed after removal of the outer wall and evacuation of the pus. But it cannot be too strongly insisted upon that there should be no waiting after a rigor has occurred during the coming of an acute or chronic middle-ear suppuration; the antrum should be at once opened and the sinus examined. An interesting point about the case related is that although the boy was perfectly well the optic neuritis was present at least three months after the operation. The giddiness which was such a marked symptom was due in all probability to disturbance of the intracranial circulation owing to the occlusion of the sinus.

GUY'S HOSPITAL.

A SUCCESSFUL CASE OF REMOVAL OF A PACKING-NEEDLE FROM THE DESCENDING COLON; RAPID DISAPPEARANCE OF INTRA-PERITONEAL ADHESIONS.

(Under the care of Mr. N. DAVIES-COLLEY.)

BY means of the Roentgen rays much assistance can be obtained in the localisation of a metallic foreign body, but a single skiagram will in many cases not be sufficient to indicate the depth from the surface. A second skiagram taken in a different direction may supply the required information, but the best method is to employ Davidson's localiser, for by its use the exact position can be readily found. Occasionally no trace of a metallic body may be found on a photograph, although the body is certainly present, and a good instance of this was described in THE LANCET of Feb. 5th, 1898, when Mr. J. H. Morgan removed a piece of stay busk from the stomach of a man; no skiagraphic shadow of the piece of metal was found because it had been lying in a position perpendicular to the sensitive plate. The rapid disappearance of peritoneal adhesions which occurred in the following case is certainly remarkable.

A married woman, aged 36 years, the mother of nine children, the last of whom had been born 15 months, was on April 12th, 1899, admitted into Guy's Hospital under the care of Mr. Davies-Colley with obstinate constipation and a painful swelling above the front half of the left iliac crest. Her

[1] Archives of Otology, vol. xxv., No. 4.

[2] Glasgow Medical Journal, October, 1899.

bowels had always been troublesome and she had sometimes gone three weeks without any action. About seven months previously she had swallowed a packing-needle stated to be about four inches long. She did not suffer much afterwards, except that she had pain at first in the upper part of her chest and then in the right iliac region. Two months before admission she noticed the present swelling. Of late she had had increased constipation and there had been no action of the bowels for four days. She had also had severe paroxysms of pain in the left side of her abdomen which came on suddenly without any cause and lasted sometimes for an hour. They "doubled her up" so that she could neither stand nor sit. She had also for a fortnight been unable to walk, the left leg appearing to drag behind.

On admission the patient was seen to be a thin, pale woman with a tender, firm swelling above the front half of the iliac crest, two or three inches in diameter. The limits of the swelling were ill defined. There was no redness or œdema, and fluctuation could not be felt. The abdomen generally was little if at all distended. The rectum was ballooned. She suffered from severe attacks of pain in the swelling, which usually came on at night. It was difficult to examine the swelling properly because it was so tender, but from the firm resistance in the centre Mr. Davies-Colley concluded that one end of the needle was embedded in the parietes at this point. Under the x rays the needle was visible lying in a nearly vertical position, but its distance from the surface was not ascertained. On the 15th an anæsthetic was given and after feeling the hardness in the middle of the swelling Mr. Davies-Colley cut down through the muscles expecting to find the point of the needle. There was some fibrinous exudation upon the transversalis muscle. At this depth, however, he thought it best to stop his dissection as he could no longer feel the projection through the tissues. It seemed to him most probable that the needle had been pushed back into the intestine, and that if so there was a fair probability of its passage per anum. The incision was brought together with sutures, but some suppuration followed, and a granulating wound was left. On May 12th the patient had not passed the needle, and she still suffered from pain and tenderness about the wound. A good radiogram had been taken which showed that the needle lay vertically about half way between the middle line and the outline of the flank. Its lower extremity was reckoned to be two and a half inches from the surface, and its upper extremity a little further back.

Under an anæsthetic Mr. Davies-Colley first tried to feel the needle but could not. He then, having scraped the granulation from the unhealed wound, increased the size of the incision, and slowly dividing the tissues, freely opened the peritoneal cavity. He had to cut through two or three layers of fibrous tissue and hardly any muscle. The peritoneum was thicker than normal but nowhere adherent to the viscera. At the back of the abdominal cavity beneath the wound there could now be felt the point of the needle through the wall of the descending colon. In order to draw the colon well out of the wound the incision had to be enlarged considerably. The walls of the bowel were thick and its surface was somewhat rough. After making a small incision upon the point of the needle it was easily pushed out. Only a trace of fæcal matter came with it. Mr. Davies-Colley then cleaned the adjacent bowel and after drawing the edges of the incision together with two Lembert's sutures of fine silk, he returned it into the abdomen and sewed up the parietal incision. The wound healed rapidly and the patient went out well on June 7th. The needle was four inches long and more than one-eighth of an inch thick, and its point was rather blunt.

Remarks by Mr. DAVIES-COLLEY.—I have thought this case worthy of record, because it would seem that upon the admission of the woman the point of the needle had penetrated the wall of the colon and the deeper layers of the abdominal parietes. Presumably at that time the descending colon was adherent to the parietal peritoneum. Nearly a month afterwards, when I operated a second time, I found the deeper layers of the abdominal wall and the peritoneum thickened by fibrous tissue, but there was no trace of adhesions between the bowel and the parietal peritoneum except a little roughness in the wall of the colon and the thickening of the peritoneum. I think, therefore, that during the short period of four weeks the adhesions which previously existed must have been completely absorbed.

ROYAL HOSPITAL, HASLAR.

A CASE OF CEREBRAL HÆMORRHAGE PRESENTING SEVERAL UNUSUAL FEATURES; NECROPSY.

(Under the care of Fleet-Surgeon G. J. IRVINE.)

IT is difficult to account for the occurrence of a hæmorrhage in the following case, for all the usual causes appear to have been absent. The fact that coma did not supervene until nearly five days after the appearance of the hemiplegia is difficult of explanation. The case well deserves to be put on record. For the notes of the case we are indebted to Surgeon M. McDougall, R.N.

A stoker, aged 19 years, was admitted into the Royal Hospital, Haslar, on Oct. 6th, suffering from disease of the brain. The patient had always been considered healthy. On the 4th he went ashore and in the afternoon complained to his friends of a bad headache. In the evening he suddenly became paralysed on the right side of the body; he did not lose consciousness at all. On the next day he was seen by a medical man and was described as lying in a state of semi-consciousness all day. There was no history of injury. On the 6th—i.e., two days after the beginning of the illness—he was admitted into the hospital under the care of Fleet-Surgeon G. J. Irvine.

On admission the left arm, the left leg, and the lower part of the left side of the face were found to be completely paralysed. The patient was quite conscious. It was 30 seconds at least before he answered questions, his replies being perfectly rational. There was no aphasia. The knee-jerks, ankle clonus, and superficial reflexes were entirely absent on both sides of the body. There was complete hemianæsthesia of the left side of the trunk, the left limbs, and the left side of the neck. Sensation appeared to be increased on the right side. He lay listlessly in bed, his face being directed straight to his front. There was most marked deviation of the eyes to the right. His tongue was dry and covered with cracked brown fur. He was passing urine and fæces under him. The pulse was 100, of average volume and compressibility. The heart's impulse was in the fifth space in the nipple line; an extremely faint systolic bruit was heard at the apex. The respiration was slightly quickened, otherwise being in no way abnormal; the pupils were equal in size and slightly contracted; both reacted to light.

On Oct. 7th the patient passed a very restless night, not sleeping at all and continually pulling the bedclothes off. He complained of pain in the head, otherwise his condition was similar to that on admission. On the 9th he was less slow in answering questions. He had difficulty in swallowing, most of the milk escaping through his lips; there was no regurgitation through the nose; the pupils were much contracted, the breathing was shallow and 20 per minute, the pulse was fairly full at 80, and the temperature was 98° F. On the 10th the patient had a good night, sleeping peacefully all night long. In the morning his pulse was very feeble, 160 per minute. The entry of air into both lungs was very bad indeed. There were a few very fine râles over both pulmonary bases. He seemed to be a little brighter than previously and answered questions almost immediately in a listless sort of way. At midday the patient was much worse; great difficulty was experienced in getting him to swallow. He was quite conscious. The pulse was very rapid and the breathing was very shallow. At 4.30 he was unconscious. His pulse was uncountable and felt like a very rapid feeble flickering—it must have been considerably over 200 a minute. The breathing was very slow and gasping; there was no stertor. At 5 P.M. the patient died.

Necropsy.—A large oval clot, semi-organised, measuring two inches by one inch by one inch, was found in the right lateral ventricle. The veins over the hemispheres were much congested. There was a thin area one-third of an inch thick of yellow softening around the clot. No lesion of the arteries at the base or on or in the brain was discoverable. The heart weighed 19 ounces, the mitral valve admitting one finger but not two. There were no vegetations or roughening whatever on the mitral or other valves, the absence of which seemed to point to a congenital stenosis of the mitral valve. No aneurysm or sign of emboli was found.

Remarks by Surgeon MCDOUGALL.—The following points about the case are thought to be of interest: (1) severe

cerebral hæmorrhage in a patient aged 19 years; (2) the absence of any apparent cause for the hæmorrhage; (3) the absolute hemianæsthesia; (4) the condition of the heart; and (5) the absence of coma until the very end.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Ophthalmoplegia Externa complicating Graves's Disease.—Action of Tetanus Toxin on Nerve-cells of the Cerebral Cortex.

A MEETING of this society was held on Jan. 9th, Mr. THOMAS BRYANT, the President, being in the chair.

A paper was read for Dr. FRANCIS WARNER, who was unavoidably prevented from being present, on a case of Graves's Disease complicated by Ophthalmoplegia Externa. The patient was a sparely built woman, aged 43 years. Her symptoms commenced with diarrhœa in January, 1890, which lasted for nine months. About 1894 there were much weakness, tremor of the hands, prominence of the eyes, and a few months later goitre appeared. She then took thyroid extract tabloids and continued them for some time. In 1893 there was partial loss of power in walking, and the goitre appeared to have subsided about this time. When seen in January, 1899, there were some palpitation and occasional shortness of breath, but no goitre; weakness, tremor, and pains in the limbs were her principal complaints. The patient was not aware of the limitation of her eye movements. Both eyes were equally prominent. Von Graefe's sign was well marked and pupillary reactions were normal. The movements of the eyes were very limited, but not equally so in each eye nor in all directions. There was marked tremor but no incoördination. There were no indications of syphilis. No marked change occurred while she was under observation. Dr. Warner referred to a case which he had published in the Transactions of the Society, vol. lxvi., which was under his care in 1882, in which the same symptoms existed in a more marked degree after subsidence of the goitre, accompanied by paresis of the face and muscles of mastication, together with severe gastric crises and much mental disturbance. The patient died in St. Thomas's Hospital in 1884, and the sequel of her case was recorded by Dr. Bristowe in his "Diseases of the Nervous System," p. 69. No distinct brain lesion was found. Mr. Arthur Maude published nine cases of Graves's disease in St. Bartholomew's Hospital Reports, vol. xxvii., 1891, and one of these patients developed sudden left facial paralysis, and two days later ophthalmoplegia externa of the left eye. Cases of partial paralysis were recorded as occurring in Graves's disease by several authors in the Transactions of the Ophthalmological Society, 1886.—Mr. JAMES BERRY asked whether there was any evidence that the patient was hysterical. Some observers had associated ophthalmoplegia externa with hysteria. Indeed, Ballet, in an exhaustive monograph on the subject, had made three groups of cases: (1) ophthalmoplegia externa with Graves's disease; (2) ophthalmoplegia with hysteria, but without Graves's disease; and (3) ophthalmoplegia with both Graves's disease and hysteria. He was under the impression that "hysteria" played a very important part in both of these conditions. He was sorry that Dr. Warner had not raised any of the interesting questions relating to the pathology or treatment of Graves's disease. The theory of its sympathetic origin, though still held by some, was, he believed, entirely erroneous, and no progress would be made until this was put aside. It was this theory which had lead to the adoption of dividing the sympathetic for the cure of the disease, but the good results, if any, had been very dubious. One patient whom he (Mr. Berry) had seen died a few hours after operation with an extremely rapid pulse. Boissou had published 27 cases of operation on the sympathetic, but only 15 of these were typical cases of exophthalmic goitre and only two of them could be described as having undergone cure. Experiments on animals were very fallacious in this domain, and in man the relief obtained by division was at most only temporary, and the event very doubtful. One of the advocates of the operation had said that he would only advise it if the cornea were in danger of sloughing. But there was at least one case which had sloughed after the operation of dividing the sympathetic. Turning to the question of pathology of the exophthalmos there were still men who believed it to be due to dilatation of blood-vessels behind the globe. But if the vessels of the orbit were congested why were not those of the conjunctiva hyperæmic? Yet these vessels were not more vascular than normal. Cases in which there was known to be venous and arterial congestion of the orbit there was always hyperæmia of conjunctivæ. The enlargement of the thyroid gland was also said to be due to the same cause, but post-mortem examination showed no dilatation of vessels. These were not larger than in ordinary parenchymatous goitre. The operation of division of the sympathetic was based on erroneous theories and he was unable to support the practice.

Mr. ALEXANDER G. R. FOULERTON and Dr. H. CAMPBELL THOMSON communicated a paper giving the results of an Investigation into the Nature of the Changes produced in the Nerve Cells of the Cerebral Cortex by the Action of Tetanus Toxin. The experiments of Wasserman and Takaki were first referred to. These experiments had demonstrated the fact that nervous tissue possessed the property of being able to apparently neutralise the toxin of tetanus. Wasserman and Takaki, in explanation of their results, had adopted Ehrlich's theory as to the chemical interaction of toxin and antitoxin to form an inert substance, just as an acid and a base combine to form a neutral salt. And the cells of nervous tissue, being of all cells the most susceptible to the action of the toxin, were assumed to be the seat of the most active production of the specific antitoxin. Roux and Borrel, following up the same lines of investigation, had confirmed the results of Wasserman and Takaki, but had explained these results in a different way. Roux and Borrel believed that the apparent neutralisation of the tetanus toxin by nervous matter was not due to its chemical interaction with a specific antitoxin, but rather to an inhibition of it by the nervous tissue comparable with the special affinity for a stain displayed by a particular tissue element. On the whole, the balance of evidence appeared to be rather in favour of the view adopted by Roux and Borrel. The questions with which the present investigation was more particularly concerned were: (1) Was the functional disturbance in tetanus the result of, or accompanied by, structural alterations in the nerve-cells of such a nature that the change could be demonstrated by microscopic examination? and, that being so, (2) were such changes specific in their character? A number of experiments were carried out in which the cerebral cortex was examined after the inoculation of tetanus toxin in rabbits, guinea-pigs, and mice. The doses of tetanus toxin varied and the animals were killed at different periods of time after the inoculation. The brains were removed immediately after death and hardened in a formalin solution; the sections were stained by a modification of Nissl's process with methylene blue. In all the animals definite changes in the staining reaction of the motor cells were found. The earliest changes appeared to take place just outside the borders of the nucleus, which presented a granular speckled appearance, while the nucleus and nucleolus retained their normal appearance. There was usually also at this stage some pallor of the cell body close to where the axon arose. These central changes gradually progressed; the outline of the nucleus at first became blurred and indistinct, and finally was completely lost. The periphery of the cell body also underwent changes which were manifested by the appearance of a darkly stained edge which contrasted strongly with the pale central area. This deep staining at the periphery was a very constant condition and was generally in evidence as soon as there was definite pallor in the centre. The nucleus in this stage was often quite indefinable; the nucleolus remained well marked, though often irregular in outline; and the cell body was altogether swollen and altered in contour. While Mr. Foulerton and Dr. Thomson believed that this description gave a fair idea of the typical appearances according to the intensity of the change, there were certain variations met with which probably represented other stages of the same process. In some the early changes appeared to occur in the neighbourhood of the axon, and this area assumed a pale granular appearance, while the central part still remained normal. In others the deeply stained area which usually borders the cell body became of much wider extent, and the cell body appeared to be divided into two parts, one of which was pale and the other very dark. The changes were thus not absolutely constant in their character, but, as might be expected, appeared to vary somewhat with the amount of the initial dose of toxin and wi h

the length of the period of intoxication. The different appearances of the nerve-cells in these experiments were, however, believed to represent different phases of the same morbid process, subject to the influence of the two factors already mentioned. Sections of the motor area of the cerebral cortex showing these changes were demonstrated under the microscope. As the result of these experiments the following conclusions were formulated. (1) Certain definite histological changes were produced on the motor cells of the cerebral cortex by the action of tetanus toxin; (2) with efficient doses of the toxin such changes were of constant occurrence; and (3) whilst the occurrence of a change of some sort was constant the exact histological appearances produced varied with differences in the accompanying factors relating to time and dose. The investigation had been conducted more particularly with reference to the nerve-cells of the motor area of the cerebrum, but evidence had been obtained that similar histological changes occurred in cells of other portions of the cerebral cortex and also in the cerebellar cortex. It was at present impossible to say whether the changes described in tetanus were absolutely specific. But whilst definite nerve-cell changes had been found to occur after the inoculation of animals with other bacterial toxins, such changes were readily distinguished from those which were obtained with the tetanus toxin. The motor disturbance which occurred in tetanus appeared, then, to be the result of definite changes in the constitution of nerve-cells of the motor areas of the spinal cord and cerebral cortex; and the incubation period in tetanus must be regarded as the time which would necessarily elapse before sufficient toxin to produce, in the case of a motor nerve-cell, motor disturbance had been taken up from the circulating blood and fixed and accumulated in the cell substance.—Dr. FREDERICK E. BATTEN asked whether the temperature might have any effect in producing the changes described. Pyrexia produced changes in the cerebral cells which somewhat resembled those described by Mr. Foulerton and Dr. Thomson. Doubtless they had excluded that fallacy. Mr. Foulerton and Dr. Thomson had found these changes not only in the motor area and cerebellum but in other parts of the cortex. But in tetanus the intellect remained clear. How was this clinical fact to be explained? If the frontal region were affected they ought to get psychical effects. He had lately examined the brain and spinal cord of a child who had died from tetanus neonatorum, using the methods of Marchi and Niessl, as well as every other method employed by Mr. Foulerton and Dr. Thomson, but the results as regarded any changes in the cerebral cells were absolutely negative. The child seemed to be about to recover and it was not until three weeks from the onset of the disease that he died, so it might be said that he was on the road to recovery, but certainly there were none of the changes described. Dr. Batten found it somewhat difficult to differentiate these changes described by Mr. Foulerton and Dr. Thomson from those due to other toxins, such as glanders or pneumococcus. But he quite admitted that a very large experience was required for the adequate study of cerebral histology and the differentiation of changes due to pyrexia, tetanus, &c., and therefore such contributions as those before the meeting were extremely valuable.—Mr. FOULERTON, in reply, said that the temperature of the animals experimented on had been taken three times a day throughout, and in no case had it risen more than 1½° above normal at any time. In the rabbits the temperature had usually, and always for several hours before death, been normal. The possible fallacy of post-mortem changes had been very carefully excluded, for the brains, in 12 instances out of 14, had been taken out directly after the animal had been chloroformed and placed at once in the preservative. Mr. Foulerton and Dr. Thomson felt certain that these changes were not the same as those produced by pneumococcus, glanders, and the other infections tried.

MEDICAL SOCIETY OF LONDON.

Excision of the Vesicula Seminalis.—Operative Treatment of Uterine Fibroids.

A MEETING of this society was held on Jan. 8th, Dr. F. T. ROBERTS, the President, being in the chair.

Mr. C. MANSELL MOULLIN read a paper based on two cases in which he had Excised the Vesicula Seminalis. In both cases the operation was performed for tuberculous disease extending upwards from the epididymis. The patients were young adults. The testis, which had in each case been involved for some time, was removed through an inguinal or inguino-scrotal incision and the cord divided as high up as possible. The patient was then placed in the lithotomy position and the under surface of the prostate and the base of the bladder were exposed through a modification of Zuckerkandl's incision. The vesicula seminalis and the termination of the ejaculatory duct were then dissected out. In one instance a small intervening portion of the vas deferens was left behind. In the other, two ligatures were placed upon the cord in the groin, one upon the vas deferens by itself and the other upon all the other structures, and the whole of the remaining portion of the vas was extracted through the perineal opening. There was very little bleeding in either case. The wounds were packed with iodoform gauze and the external sphincter was sutured to the centrum tendineum. One healed up without inconvenience; in the other, in which the ejaculatory duct had been torn out from the urethra, a small urinary fistula persisted for some months, a few drops coming through on micturition. There was no fever in either and the action of the external sphincter was not impaired in any way. Mr. Moullin strongly advocated complete removal of the vesicula seminalis and vas deferens in every case of tuberculous disease of the epididymis in which the vesicula could be felt distinctly through the rectum, with the view of clearing out the whole disease and of giving the patient one more chance of recovery before the bladder became hopelessly involved, and probably saving him from a serious and otherwise ultimately fatal disease.—Mr. F. SWINFORD EDWARDS remarked on the novelty of the subject. He had not performed the operation, but he had seen one case operated on. It was done for tuberculous disease of the vesicula. The operation was not a simple one. It certainly required a good deal of time and probably entailed considerable hæmorrhage. It had occurred to him that the vesicula might be brought into view better by an operation of a modified kind resembling Kraske's operation for excision of the rectum. He would like to ask Mr. Moullin if he would recommend the procedure in cases of gonorrhœal vesiculitis? He had treated one such case satisfactorily by a kind of massage through the rectum. He would also like to ask what was likely to be the result of such operations. Would any variety of fistula be likely to be left? He congratulated Mr. Moullin on bringing the subject to the notice of the profession.—Mr. F. C. WALLIS thought that Mr. Moullin had not sufficiently alluded to the difficulties which attended such an operation. These were very considerable and a less experienced operator than Mr. Moullin would find himself in grave difficulties. He would be glad if Mr. Moullin would refer to this in his reply.—Mr. MANSELL MOULLIN, in reply, said that he did not think there were any very great difficulties provided the patient was placed in the lithotomy position with the buttocks well raised. It was surprising how well the structures came into view. In old men difficulties with the prostatic plexus might arise, but the hæmorrhage was not serious in younger subjects. The structures to divide were singularly few. Moreover, he had found that pressure, applied over the pubes above the symphysis in young subjects, especially those affected by tuberculous disease, could drive the base of the bladder and vesicula right down to the perineum. He referred to a case on which he had operated for gonorrhœal vesiculitis which had been under observation for 18 months. The operation was more difficult than those he had referred to in his paper because of the adhesions. The patient had been variously treated before without success, but this treatment of removal was efficacious. He very much doubted whether the structures could be more completely exposed by a modified Kraske's operation and this would involve a more severe degree of shock and a much longer operation. He thought the vesicula could be exposed better by a semilunar incision such as he had described.

Dr. W. J. GOW read a paper entitled Some Remarks on the Operative Treatment of Uterine Fibroids. The operation chiefly referred to was abdominal hysterectomy with intraperitoneal treatment of the stump, and the remarks were founded on 47 cases of this operation performed by him on cases of fibroid. The indications for the operation were, he said, closely bound up with the mortality from the operation. So long as this remained as high as 10 per cent., or even less, the operation must necessarily be restricted to cases where life was threatened. If the mortality were low it might fairly be advised in cases where the symptoms were sufficiently severe to cause invalidism.

Among the 47 cases recorded without selection by him of abdominal hysterectomy for fibroids where the stump was treated intra-peritoneally there was only one death, giving a total mortality of slightly over 2 per cent. The fatal case was due to secondary hæmorrhage occurring 36 hours after the operation. There were in the series 39 consecutive cases of recovery. He advised that after the uterine arteries had been tied, a precautionary ligature, including the outer fourth of the stump on either side, should be employed. By this means all oozing or spouting from the stump was checked. Such ligatures did no harm. The real essential to success was complete asepsis and complete control of bleeding vessels. He also urged the desirability of the simplification of abdominal operations. One assistant was all that was necessary and six sponges and six pairs of pressure forceps were usually amply sufficient. The fewer people engaged within the circle of the operation the better. He considered that it was most desirable to leave one or both ovaries, as in this way the climacteric changes took place slowly instead of suddenly. In four of his cases of hysterectomy a pyosalpinx was present on one or both sides, but no bad consequences followed. In only one of these cases was drainage employed. The presence of adhesions proved to be the most serious complication at the time of the operation, on account of the risk of hæmorrhage when they were torn through. He supported the view that of all the radical operations for fibroids abdominal hysterectomy with intra-peritoneal treatment of the stump was the best, and this operation might in the future be confidently expected to give a mortality of not more than 1 or 2 per cent.—Dr. GEORGE F. BLACKER congratulated Dr. Gow on his brilliant results—results which certainly had not been exceeded in this country, if indeed they had in any other. The question of operation on uterine fibroids had undergone very great alteration of late years, and if the mortality of abdominal hysterectomy could be reduced to that of ovariotomy, or lower, it would revolutionise their methods of treatment. The worst complication of the operation itself was undoubtedly the presence of adhesions. He referred to a case which had been admitted moribund. Abdominal hysterectomy was attempted but it was found to be impossible. At the necropsy they found a large fibroid with three-quarters of a pint of pus in its interior. The method of operating he had followed was that of Kelly. He preferred the intra-peritoneal method of dealing with the stump.—Mr. F. C. WALLIS remarked that he had helped Dr. Gow in many of his operations and he believed that the extreme simplicity of his methods constituted the chief source of his success. In some operations he had seen it was surprising what an immense number of instruments, assistants, sponges, &c., were employed. This greatly increased septic risks.—The PRESIDENT remarked on the extreme importance of adhesions in all operations of this kind.—Dr. GOW, in reply, said that undoubtedly adhesions constituted the chief source of danger at the operation as they gave rise to oozing. This led to operating against time, for nothing could be done until the uterine artery could be got at. He had a prejudice against packing the pelvis with gauze. Draining, though rarely necessary, became necessary under these circumstances, when adhesions were very plentiful. His main objects in bringing the subject forward had been to advocate the operation as a means of relief in bad cases of fibroid and to emphasise the intra-peritoneal method of dealing with the stump.

OBSTETRICAL SOCIETY OF LONDON.

Treatment of Rupture of the Uterus by Packing the Tear with Iodoform Gauze.—Exhibition of Specimens.

A MEETING of this society was held on Jan. 3rd, Mr. ALBAN DORAN, the President, being in the chair.

Dr. HERBERT SPENCER read a paper on four cases of Rupture of the Uterus Successfully Treated by Packing the Tear per vaginam with Iodoform Gauze. They were the only cases in which he had adopted this method of treatment and the only cases which he had known recover. All the others (about eight in number) had died in a few hours from shock and hæmorrhage or in a few days from sepsis. Twice he had performed abdominal hysterectomy with a fatal result. After quoting some remarks which he made in the "Obstetrical Transactions" for 1897 upon the great danger of the operation of abdominal hysterectomy in patients suffering from shock consequent upon rupture of the uterus he expressed the belief that the mortality from rupture of the uterus might be lessened by the use of gauze packing. Having alluded to the advocacy of gauze packing by others he expressed his own views, for the purpose of discussion, as follows. In the treatment of rupture of the uterus—1. Abdominal section was rarely required and almost solely in cases where the fœtus had passed completely or in great part into the peritoneal cavity. It should be performed rapidly under local infiltration anæsthesia and should be followed by flushing of the peritoneal cavity with normal salt solution and by suture of the tear, if possible, or, if this be not possible, by packing the tear with iodoform gauze and draining by the vagina or abdomen. 2. Abdominal hysterectomy was hardly ever necessary; when the broad ligaments were so much damaged as to endanger the vitality of the uterus vaginal hysterectomy should be performed. 3. All incomplete tears implicating the broad ligament and most complete tears should be treated by packing the rupture per vaginam with iodoform gauze after removing clots and fluid blood.

Dr. PETER HORROCKS thought that a very strong distinction should be made between cases of laceration of the cervix and rupture of the body of the uterus. In two of Dr. Spencer's cases the laceration had not penetrated the peritoneal cavity. Such cases often did well without any gauze packing, and indeed without any treatment at all, and the chief point was to stop hæmorrhage and to see that everything was done aseptically. He had had several cases in which the peritoneal cavity had been opened by the rupture and the results had been highly satisfactory in recent years. He attributed this not alone to the packing by gauze but to the fact that the labours had been conducted aseptically. He gave details of a case in which the rent was sewn up, but the patient died in 48 hours. In another case he had put in two stitches so as to draw the gaping wound together somewhat and then he packed with sal-alembroth gauze, which was removed every 12 hours under chloroform for the first few days and once a day afterwards. The patient made an excellent recovery, but one of the stitches gave trouble and had to be removed nine months later; she had since had a living child, the labour having been brought about at the eighth month. He gave details of three other successful cases in which sal-alembroth gauze was used and tincture of iodine solution as a douche. In his opinion Dr. Spencer had left the gauze in too long and that the best treatment in cases which could not be treated in the way above-mentioned was to open the abdomen and to sew up the tear with sterilised silk. He gave details of a case in which this had been successfully done and the patient recovered, although the abdominal wound burst open and the bowels protruded on the tenth day. He saw no reason to change sal-alembroth gauze for iodoform gauze.

Dr. G. E. HERMAN said that the suture of a ruptured uterus was useless unless the edges of the wound were brought accurately together throughout its whole length; one or two sutures far apart were worse than useless. In cases in which complete suture of the wound could not be done he thought packing with iodoform gauze was the best practice. If the rent was so situated that packing with gauze was impracticable he thought that vaginal hysterectomy would give the patient the best chance.

Dr. A. H. N. LEWERS said he had had a case of rupture of the uterus at the London Hospital about 18 months ago in which iodoform gauze packing was adopted and the patient, though very ill for a week, recovered. Dr. Lewers believed that iodoform gauze varied a good deal in strength and except when the less highly iodoformed gauze was employed there was a good deal of danger of iodoform poisoning; he had of late used carbolic gauze in the peritoneum with satisfactory results.

Dr. DRUMMOND ROBINSON was much interested in the subject. He had had three cases of ruptured uterus under his care. In one case the patient died within a couple of hours from a complete rupture. The other two cases recovered. The first of these was an incomplete rupture into the left broad ligament; there was very little hæmorrhage at the time or afterwards. No drainage was employed and the patient recovered. The second successful case was that of a multipara, of about 40 years of age, delivered by forceps. The tear (a complete one through the cervix and lower segment anteriorly) was packed with cyanide gauze. The

patient was very ill for a fortnight but subsequently made a good recovery and had given birth to another child quite normally. A few days after the rupture a sinus developed at the umbilicus; this healed up in a few days.

The PRESIDENT said that absorption of iodoform caused rapid pulse, which was very confusing, as it might be taken as a symptom of sepsis. Many foreign authorities objected now to iodoform or any other chemical antiseptic agent in packing wounds. Did Dr. Spencer hold that the iodoform in gauze was an active antiseptic germicidal agent?

Dr. HERBERT SPENCER, in reply, said that two of his cases were complete ruptures and two were incomplete. The distinction between laceration of the cervix and rupture of the body of the uterus could not be sharply drawn; most cases of the latter did actually involve the cervix. Slight cases of laceration of the cervix up to, or even beyond, the vaginal insertion were of small importance; but where, as in his two cases, the cervix and lower segment were lacerated so extensively as to admit the half-hand into the broad ligament and there were much hæmorrhage and shock the danger was great; the extent of the laceration in the uterus was of less importance than the extent of the laceration of the vessels and tissue of the broad ligament; he had known death to occur where a cervical laceration was so short as not to involve either os. It was his experience and belief that these severe incomplete lacerations actually killed more women than the complete ones. He wished again to emphasise the great danger of abdominal section in rupture of the uterus and agreed with the remarks of Dr. Herman as to the uselessness of partial suture. He considered it undesirable to inject an irritant like iodine solution into the peritoneal cavity and dangerous to give chloroform and change the gauze every 12 hours. Iodoform gauze might be left in for six days or longer. The cases related by other speakers strengthened his belief in the value of gauze packing; though iodoform gauze was not free from risk he believed that in anæmic cases like those under discussion it was less dangerous than cyanide or carbolic gauze or even sterilised gauze which would not long remain aseptic in the vagina.

The following specimens were shown:—

Dr. T. W. EDEN: (1) Adenoma of the Uterus; and (2) Cast of the Uterus.

The PRESIDENT (for Dr. PAWLIK of Prague): (1) Photograph of Primary Cancer of the Fallopian Tube; and (2) Macerated Fœtus successfully removed from the Abdominal Cavity two months after Spurious Labour.

Mr. J. D. MALCOLM: Bilateral Pyosalpinx, Communicating.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Jan. 4th, Mr. H. E. JULER, the President, being in the chair.

The PRESIDENT showed a case of Orbital Exostosis. The patient, a young woman, had first come under observation in 1892, when there was a small, hard, nodular mass in the inner angle of the left orbit fixed to the nasal process of the superior maxillary bone. It had blocked the nasal duct, causing a mucocele, and the lower canaliculus was slit up. In 1894 the tumour seemed to be a little larger. No change seemed to have occurred since 1897; there was slight proptosis and the eyeball was displaced to the outer side, but there was no diplopia. Opinions were invited as to the desirability of removing the tumour.—Mr. E. W. ROUGHTON advised the removal of the tumour and thought that the best instrument for the purpose would be the surgical engine.

Mr. FRANCIS JAFFREY showed a case of Coccygeal Teratoma. It was that of a female child, aged six months, one of twins, who was admitted into the Belgrave Hospital for Children in September last with a large tumour in the coccygeal region, which was partly fluid and partly solid, and which at first sight appeared to be either a spina bifida or a dermoid, but on closer examination proved to be a case of teratoma. On examination the skin was found to be very thin in parts and on grasping the swelling a lobulated mass could be felt. The tumour had increased in size since the admission of the child into the hospital. It had been tapped twice and some fluid like turbid beer had been removed; this fluid was examined at the Clinical Research Association who reported that from chemical analysis it was quite evident that the fluid was not cerebro-spinal in origin. It contained none of the albumose characteristic of that fluid, nor, on the other hand, did it correspond to amniotic fluid. The cyst in question had probably arisen in the usual manner of congenital cysts in that region—viz., as representative of an attempt at another embryo.—Mr. RAYMOND JOHNSON did not regard the evidence that the tumour was a teratoma convincing. It was probably one of the more common multilocular cystic tumours occurring in this region. The tumour probably extended up between the sacrum and rectum and its removal would involve a more extensive operation than the child could at present stand.

Mr. HUBERT PHILLIPS showed a case of Deformity of the Left Arm in a youth, aged 17 years. There was considerable shortening of the humerus and what appeared to be the upper extremity of that bone was seen projecting on the inner side of the arm when the biceps was called into action. One extraordinary feature of the deformity was the fact that nothing abnormal was noticed by the parents or others until the patient fractured his right arm about nine years ago. With regard to treatment Mr. Phillips considered that surgical interference was not only not called for but that it would be absolutely injurious, as the arm was a most useful one in every way.—Mr. E. W. ROUGHTON and Mr. JACKSON CLARKE regarded the deformity as the result of a fracture of the upper part of the shaft of the humerus which had united at an acute angle.—Mr. PHILLIPS, in reply, agreed with this opinion.

Mr. JACKSON CLARKE showed a man, aged 37 years, who sustained a severe Compound Comminuted Fracture of Both Bones of the Left Leg in July last. A segment of the tibia measuring three inches in length had to be removed because it was quite separated from its periosteal connexions and was contaminated by dirt from the roadway. An incision was made over the lower part of the fibula and several fragments of this bone were removed in order that the two remaining segments of the tibia could be approximated and fixed by a suture of silver wire. The limb was treated by the open method and recovery was uninterrupted. A portion of the silver wire that had been exposed in the inner wound became gradually surrounded by callus. The patient had now a useful limb in which three inches of shortening was compensated for by a raised boot. Three months after the accident Mr. Clarke allowed the patient to walk with the help of lateral supports of iron fitted into the boot below and extending to the knee above. Six months after the fracture a skiagram was taken and although abundant firm bony callus was present the skiagram showed no trace of it.—In reply to Mr. JAFFREY Mr. CLARKE said that he hoped to have skiagrams taken from this case from time to time in order to help to settle the point as to when the consolidating bony callus became recognisable. Mr. Clarke had no doubt that the union was bony and not fibrous; the appearance of mobility noticed by Mr. Raymond Johnson, he thought, was due to the proximity of the ankle-joint.

Dr. JAMES TAYLOR showed two cases illustrating the Results of Anti-syphilitic Treatment in Syphilitic Disease of the Brain. The first was that of a woman whom he had brought before the society 18 months previously and who at that time had right-sided hemiplegia following typical Jacksonian epilepsy. The patient had been treated with iodide of potassium and mercury with complete success. The second case was that of a man who was at first believed to be suffering from ordinary epilepsy. The attacks were, however, followed by left-sided hemiplegia, headache, and optic neuritis. Iodide of potassium was given internally and mercurial ointment used as an inunction. After a considerable time the fits ceased and the other symptoms improved, but recurred with cessation of the treatment. The latter was resumed and now the patient only presented a very slight degree of weakness, especially in the left leg, and occasional faint attacks.—The cases were discussed by the PRESIDENT, Mr. JACKSON CLARKE, Dr. L. G. GUTHRIE, and Dr. G. A. SUTHERLAND, and Dr. TAYLOR replied.

Dr. LEONARD GUTHRIE showed a case of Tabetic Ophthalmoplegia. The patient was a man, aged 65 years, who seven months previously had suddenly developed ptosis of the left eyelid with crossed diplopia and external strabismus. For 12 months he had suffered from weakness and unsteadiness of gait, giddiness, and tremors of the head and the right arm. Two years ago he had had some kind of a fit attended by momentary loss of consciousness, but no similar attack had occurred since. He had had a chancre followed

by non-suppurating bubo and severe sore-throat at the age of 24 years. He had been for six months under observation, during which time the ptosis had become less marked, but the left eyeball deviated outwards as before and could not be moved upwards or inwards beyond the mid-line. Quite recently the right eyeball also could not be moved inwards beyond the mid-line or upwards, but its movements outwards and downwards were unimpaired. The pupils were moderately contracted and reacted little, if at all, to light. Accommodation could not be tested owing to loss of convergence. The knee-jerks present six months ago had gradually disappeared. The patient's gait had become more ataxic and Romberg's symptom was now manifest. Sensation was unaffected except that the ulnar nerves behind the inner condyles were abnormally insensitive. He had some difficulty in holding his urine. There were no lightning pains. Dr. Guthrie considered that the diagnosis of tabes was now obvious, although six months previously the presence of tremors and the absence of any definite signs of the disease, including that of lightning pains, had created doubt as to the nature of the case. He drew attention to the frequent occurrence of paralysis of the ocular muscles as pre-ataxic symptoms. Such cases of ocular paralysis usually came under the notice of ophthalmic surgeons and were frequently cured, or the paralysis spontaneously subsided, perhaps years before other signs of tabes appeared.—The PRESIDENT and Dr. JAMES TAYLOR discussed the case and agreed upon the frequency of ocular paralysis in the early stages of tabes. Dr. Taylor had seen a number of such cases at the London Ophthalmic Hospital and had usually found the knee-jerk still present. The paralysis was usually transitory, but it might be permanent and was then probably due to nuclear changes.

Mr. E. W. ROUGHTON exhibited a case of Congenital Dislocation of the Hips. The patient, a man aged 20 years, showed the characteristic appearances of a bilateral dislocation.—Mr. JACKSON CLARKE remarked upon the favourable results which had been obtained in the treatment of this deformity in early life by Lorenz's bloodless method — Dr. G. A. SUTHERLAND and Dr. J. TAYLOR also spoke and Mr. ROUGHTON replied.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

The Open-air Treatment of Consumption.

AT the December meeting of this society, Dr. C. E. BEEVOR, the President, being in the chair, the following discussion on the Open-air Treatment of Consumption took place.

Dr. CLIFFORD BEALE opened the discusssion, pointing out that while fresh air had from the earliest times been recognised as an essential to the successful treatment of tuberculous diseases it had of late become more evident that purity of air whether in open or enclosed spaces was the first consideration. The highest physiological perfection among human beings was to be found amongst peoples who lived in the purest air. Impurity might be organic or inorganic, but of these the organic contaminations were by far the most important as being direct feeders of the micro-organisms infesting the air passages. Inorganic contamination was for the most part injurious as the carrier of micro organisms and of organic matters. The tuberculous patient suffered from the effects of the toxin produced in the formation of the tubercle and no remedy short of an antitoxin capable of annulling the effects of the poison within the body could be expected to have any curative effect. To prevent the entrance of the bacillus and to deprive it of the surroundings in which it flourishes must be the main aim of treatment. Air in enclosed spaces occupied by one or more animals, human or otherwise, must be more or less contaminated. Hence tuberculous patients should be kept away from crowded spaces and taught to regard such places as direct feeders of the disease. The living rooms must be kept free from stagnant air and should be well flushed with fresh air at all times when unoccupied. In the early stages the disease resembled a battle where bacillary attack had to be met by physiological defence and the defence was at first in superior strength. Opportunity had to be seized to assist that defence while it was still strong. Hence the vital importance of placing the patient under strict hygienic rules at the outset. Exercise, sleep, and food had all to be regulated and systematised and more attention was paid to such a system if it was written or printed in full for the patient's guidance. Medical supervision to see that the system was adhered to was an essential without which the formulation of rules was useless. Treatment was best carried out away from the home, but banishment to foreign surroundings was not essential. The length of time required was best left indefinite. It was always difficult to get the patient to see the necessity for making a sacrifice of time and money in the early stages when he did not feel really ill, but with the experience of recent times such a sacrifice should be urged in all really incipient cases.

Dr. F. R. WALTERS expressed his complete agreement with Dr. Clifford Beale's admirable summary of the principles of open-air or hygienic treatment of consumptives. The following remarks would be limited to such treatment in sanatoria and similar institutions. The open-air treatment did not merely consist in exposure to fresh air while leaving the patient to his own devices, but was a combination of hygienic remedies requiring judgment and experience and calling for more or less continuous supervision by the resident medical officer. The treatment was educational and progressive—a species of training, mental and physical. The amount and nature of exercise must be determined partly by observation of actual results in each case; and the same with other hygienic remedies. Treatment in a sanatorium had the advantages common to all hospital treatment, viz., those which arose from coöperation and from the supervision of a number of more or less similar cases by one medical man in the same place, greater economy, and greater efficiency. The disadvantages were purely sentimental in any properly managed sanatorium. Although the locality was by no means a matter of indifference and most of our urban chest hospitals were ill suited for the open-air treatment, the Hampstead Chest Hospital was exceptionally favoured in its position, and the results there had been very satisfactory. The dense fogs did not usually reach the hospital and thin white fog was not found to do harm. The winter cold was no drawback, and night air was also found to be quite harmless. Some of their patients had slept out of doors continuously in a tent or on the balconies with distinct advantage. The arrangement of the wards in a double row was a drawback, as it was more difficult to ensure free ventilation from back to front. The new galleries would, however, be a great help. Prolonged treatment for 12 months or more was nearly always essential in dealing with poor people. As this long period could not usually be passed in the chest hospitals these should become affiliated with country sanatoria and the patients should be sent on as soon as they were able to travel. The true function of a chest hospital was to give "first aid" to the consumptive, the bulk of the treatment being carried out in a suitable country place.

Dr. EDWARD SQUIRE said that the "open-air treatment" of consumption was a development of the treatment of hygienic measures which tended to strengthen the resisting power of the tissues against the effects of the tubercle bacillus. It had long been recognised that attention to hygienic requirements was one of the best means of preventing tuberculosis in the individual, and the principle of the "hygienic treatment" might be expressed in the words which he quoted from a book which he published seven years ago:—"The hygienic rules so important as preventive measures are equally necessary conditions in the treatment of the disease." Of these requirements pure air was undoubtedly one of the most essential, but the food and clothing, the proper proportion of exercise and rest, and methodical regularity of life required careful attention. It was in special institutions such as hospitals and sanatoria that these requirements could be most completely provided, for in these the patient was subject to rules, and supervision ensured obedience to the regulations. But many cases could not, and some would not, enter an institution, and those who were admitted could not be kept indefinitely. Hygienic treatment at home, which was the special subject he had been asked to speak about, could be carried out with great advantage, although rarely with the completeness which was possible in a sanatorium. He had had most encouraging success with such treatment. Rules must be drawn up and written out or printed regulating the daily life of the patient, giving information about ventilating his rooms and the disposal of the sputa, stating the times and quantity of his meals, the times for rest and for exercise,

&c. To ensure the carrying out of details the personal supervision of the medical attendant was needed, and a nurse who had some experience of the treatment was valuable. It might be desirable for the patient to leave home and he had obtained good results by advising the patient to move from place to place "chasing the sunshine," staying a few weeks in one place and selecting suitable parts of the country. One disadvantage of home arose from the wish of the patient's family to spend some part of the day with him, for they sometimes found his rooms too freely ventilated for their liking and persuaded him to sit in a close atmosphere, perhaps in the evening, when all the family met in one room, with the gas lighted and the curtains drawn. Although it was only in the early cases that they might hope for a cure, advanced cases were the better for hygienic treatment, and not only was the patient's condition improved, but attention to hygiene diminished the risk to other members of the household. They might not be able to ensure perfect hygienic conditions in the home, but that was no reason for saying that the treatment was impossible at home. If they could not get all the hygienic requirements which they wished they should at least get for their patients as many as they could, and he had seen benefit result from even such a modified hygienic treatment as was possible amongst those who were not too well off and who could not leave London. Hygienic treatment did not absolutely replace drug treatment—drugs might be needed to assist appetite, to relieve cough, or to procure sleep. Finally, he would emphasise the necessity for early diagnosis, since cure was only possible in the early stage; when there was any suspicion of possible tuberculous mischief to examine the chest fully and methodically. Failure to detect early disease was, he believed, more often due to incomplete examination than to inability to appreciate the slight but distinct physical signs which indicated commencing tuberculosis in the lungs.

Dr. CHOWRY-MUTHU in the course of his remarks referred to the sanatorium treatment of phthisis as carried on at Ventnor. He said the open-air treatment was in the experimental stage in this country. Though beset with difficulties it could be successfully carried out in England. The secret of success in treatment depended upon thorough organisation, strict attention to each detail, the strong personality of the medical attendant, and his wisdom in distributing the different elements, as pure air, good food, exercise, rest, &c., according to the needs of the individual patient—in short, in directing and controlling the whole movement. He pointed out that the open-air life led by the ancient Greeks was one of the factors that contributed to their health and intellectual greatness. An indirect result of the agitation for fresh air in health as well as in disease would be the extension of the principles of the new treatment to every-day life. There would be larger and more commodious schools for children, better houses for the poor, wider streets, and more open spaces.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—At a pathological evening on Dec. 21st, the President, Dr. D. Burgess, being in the chair, the following microscopic and macroscopic specimens were exhibited and briefly discussed. Microscopical preparations: Dr. A. Anderson: Typhoid Bacilli in the Urine of a Typhoid Patient.—Dr. Arthur J. Hall: (1) Various Pathological Sections from Specimens sent to the Laboratory; and (2) Blood Films stained by Various Methods.—Dr. J. Robertson: Malaria Parasites in Different Forms of Malaria and in Mosquitoes.—Dr. G. Wilkinson: Sections and Culture Preparations of Malignant Pustule.—Macroscopical Specimens: Mr. C. Atkin: (1) Intussusception with Gangrenous Gut; (2) Relapsing Appendicitis (two specimens); (3) Epithelioma of the Tongue; and (4) Epithelioma of the Lip (two specimens).—Dr. Burgess: (1) Tuberculous Meningitis; (2) Tuberculous Tumour of the Pons; (3) Hydatid of the Lung; (4) Aneurysm Rupturing into the Trachea; (5) Typhoid Ulcers; and (6) Heart: Calcareous Coronaries.—Dr. W. T. Cocking: (1) Pulmonary Abscess; and (2) Unusual case of Fibrosis of the Pleuræ and Pericardium.—Mr. A. W. Cuff: (1) Bronchial Cast from case of Plastic Bronchitis; and (2) Tumour Cerebelli.—Mr. R. Favell: Carcinoma of the Cervix complicated by Pregnancy; Successful Hysterectomy.—Dr. Arthur Hall: (1) Ichthyosis Hystrix Linearis; (2) Lardaceous Kidney; (3) Lardaceous Spleen; (4) Secondary Carcinoma of the Lung and Diaphragm; (5) Specimens Illustrating Dissemination of Tubercle from Old Caseous Bronchial Glands; (6) Alimentary Canal from a case of Nitric Acid Poisoning; and (7) Various Specimens of Heart Disease.—Mr. Arthur Hallam: (1) Tuberculous Nephritis, Nephrectomy; (2) Epithelioma of the Tongue; (3) Relapsing Appendicitis (two specimens); and (4) Scirrhus of the Breast.—Mr. H. Lockwood: (1) Calculus formed round a Hairpin removed from a Female Bladder; and (2) Foot with Ulcerating Tophi requiring Amputation.—Mr. R. J. Pye-Smith: (1) Sarcoma of the Femur; (2) Fracture of the Radius; (3) Ruptured Appendix; (4) Epithelioma of the Penis (two specimens); (5) Dermoid Cyst of the Intestine; (6) Tubercle of the Larynx; and (7) Carcinoma of the Pancreas and the Liver.—Dr. Robertson: (1) Tuberculous Spleen (Pig); (2) Tuberculous Udder (Cow); and (3) Tuberculous Pericardium (Ox).—Dr. W. J. N. Vincent and Dr. R. W. Gilmour: (1) Tuberculous Tumour of the Pons; (2) Dura Mater from Pernicious Anæmia; and (3) Ulceration of the Aorta from a Needle in the Œsophagus.—Dr. Sinclair White: (1) Fibroma Uteri (two specimens); (2) Carcinoma Uteri (two specimens); (3) Scirrhus of the Breast (five specimens); (4) Carcinoma of the Intestine (two specimens); (5) Kidney (Pyelonephritis); (6) Ruptured Kidney, nephrectomy; (7) Sarcoma of the Kidney; and (8) Epithelioma of the Penis (two specimens).—Dr. G. Wilkinson: (1) Malignant Pustule; (2) Melanotic Sarcoma of the Skin; (3) Sarcoma of the Head of the Tibia; (4) Cystic Kidneys; (5) Old Blood Cyst Removed; and (6) Ovarian Cyst.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 5th, Dr. J. B. Ball, the President, being in the chair.—Mr. Percy Dunn in a feeling and appreciative speech proposed a vote of condolence and sympathy with the family of the late Sir James Paget, an honorary member of the society.—The proposal was seconded by Mr. Swinford Edwards and carried unanimously.—The Secretary read the report of the committee appointed at the ordinary meeting on Dec. 1st to organise a scheme for gratuitous attendance on distressed families of soldiers. The committee reported that 203 members of the society had written offering to coöperate in the scheme. Of these replies 44 were from consulting physicians and surgeons and from men practising in various special departments. The remaining 159 were from men in general practice.—Mr. L. A. Bidwell read a paper on Surgical Treatment of Dilated Stomach. The principal causes of dilated stomach were: (1) cicatricial contraction of the pylorus; (2) malignant disease; (3) adhesions outside the pylorus; (4) gastroptosis; (5) spasm of the pylorus; (6) floating kidney on the right side; and (7) atony. Only the first three of these various conditions were discussed at length by Mr. Bidwell. With regard to diagnosis, the following principal methods of examining the stomach were advocated: (1) inspection; (2) palpation; (3) percussion; (4) auscultation; (5) intubation; (6) artificial distension of the stomach with gas; and (7) chemical examination of the stomach contents. The indications for operation on the dilated stomach were: (1) pain usually localised to the pyloric region and felt in the back; (2) signs of dilatation of the stomach; (3) vomiting of solid food; (4) absence of free hydrochloric acid from the vomit; (5) some emaciation; and (6) obstinate constipation. The surgical procedures which were undertaken for the relief of dilated stomach were—for malignant diseases: (1) pylorectomy; and (2) gastro-enterostomy. In non-malignant stenosis: (1) pyloroplasty; (2) gastro-enterostomy; (3) Loreta's operation; (4) pylorectomy; and (5) division of the adhesions. In neurotic cases: (1) lavage; (2) massage; (3) gastropexy; and (4) an operation for diminishing the capacity of the stomach by folding in a portion of the redundant wall. The paper was illustrated by 16 cases operated on by Mr. Bidwell and arranged in tabular form. 11 were cases of malignant disease; five of these died within a fortnight, the remaining living some months. There were five cases of non-malignant stricture which were all cured by operation. Of the malignant cases seven were gastro-enterostomies with three deaths, three were pylorectomies with one death, and one was a case of pyloroplasty which proved fatal.—Remarks were made by the President, Mr. Swinford Edwards, Mr. C. B. Keetley, Mr. McAdam Eccles, and Mr. R. Bevan.—Mr. L. A. Bidwell briefly replied.

Reviews and Notices of Books.

System of Diseases of the Eye by American, British, Dutch, French, German, and Spanish Authors. Edited by WILLIAM F. NORRIS, A.M., M.D., and CHARLES A. OLIVER, A.M., M.D., of Philadelphia, Pa., U.S.A. Volume IV., Motor Apparatus, Cornea, Lens, Refraction, Medical Ophthalmology. With 51 Full-page Plates and 211 Text Illustrations. London and Philadelphia: J. B. Lippincott and Co. 1900. Pp. 949. Price 21*s.* net.

THE first section of the book is by Professor Edmund Landolt of Paris and deals with the Anomalies of the Motor Apparatus of the Eyes; it has been well translated by Dr. C. M. Culver of Albany, U.S.A. After some preliminary observations of a general character Dr. Landolt, who, it is well known, has long been engaged with the study of the ocular muscles, describes each in turn and shows by strongly marked black and red lines the relative position of the double images in paralysis of each muscle, which is a considerable help in effecting the diagnosis of these difficult cases. He gives a drawing of an instrument that he has devised, and to which he has given the name of "ophthalmotrope," by which the movements of the globe under the several muscles and the effects of their paralysis can be identified. Dr. Landolt gives a recommendation that will, as he says, avoid promenades with a lighted candle—namely, to leave the flame *in situ* and to change the position of the patient's head, so that to make him look upward his face is directed downward, in order to make him look downward his face is directed upward, and in order to cause him to look to the left his face is turned towards the right. He considers that there are three methods of measuring the amount of deviation or strabometry, first by means of the corneal reflex, secondly by means of tangents, and thirdly by means of prisms. In regard to the etiology of the paralysis of the ocular muscles Dr. Landolt omits the lesions of the nerves in their intra-cerebral course and of their nuclei because these are elsewhere fully described. He gives as the most common causes of paralysis pressure occasioned by hæmorrhage, by exudations accompanying meningitis, and by tumours. In addition he enumerates as occasional causes syphilis, rheumatism, inflammation of the cellular tissue of the orbit, and congenital defects. Lastly, he alludes to some exceptional and perhaps unique causes, such as cystic degeneration of the pineal gland, inflammation of the mucous membrane of the antrum of Highmore, dental caries, serous degeneration of the muscles in progressive anæmia, and to those obscure cases which occur after hysterical diphtheritic attacks, in poisoning by lead, after the use of diseased meat, from excess in tobacco and alcohol, and as an accompaniment of tabes dorsalis, cases of all of which conditions are to be found scattered in medical literature. Dr. Landolt discusses at considerable length the use of prisms as a means of correcting the distressing symptom of double vision. These, though theoretically very valuable, in practice are much limited in their application in consequence of their weight, when exceeding 3° for each eye. In the operative treatment he is a strong advocate for tenotomy of the muscle of one eye, conjoined with advancement of the opposite muscle in the other eye; thus, to take an extreme case, in total paralysis of the external rectus of the left eye, he would perform an energetic advancement with resection of the external rectus on the diseased eye and a simple advancement of the same muscle on the unaffected eye. If the effect is not then satisfactory the tenotomy of the internal rectus of the diseased eye would be added. For the determination of insufficiency of convergence and the degree of insufficiency Dr. Landolt has devised an instrument consisting essentially of a Herschel's double prism, two prisms of equal power being set in a frame which enables them to revolve, and either to neutralise or to double the effect of each. The angle of deviation produced is marked by a scale. The whole of this long section is worthy of study, written as it is by one whose knowledge and experience are exceptionally large.

The section of Diseases of the Cornea is written by Dr. J. P. Nuel of Liége and Dr. Thomas H. Fenton of Philadelphia. Affections of the cornea constitute about one-third of all ophthalmic diseases and as they frequently lead to impairment of vision are therefore amongst the most important of those diseases. The article opens with a quite original and very interesting description of the microscopical appearances following clean cuts of the cornea in the rabbit, commencing two hours after the lesion, and particularly interesting as showing the conditions that obtain at the close of the second day when a layer of epithelial cells continuous with those on the surface of the cornea lines the whole surface of the cut. The valuable investigations of Leber and Metchnikoff on the changes that occur as the result of the penetration of pathogenic microbes into the substance of the cornea, such, for example, as the production of œdema and of a zone of leucocytes to limit their action, the latter possibly possessing a dialytic substance to aid the action of the macrophagic cells, which constitutes so important a chapter in general pathology and the details of which are so clearly visible in the transparent tissue of the cornea,—are all very fully described.

In regard to the treatment of pannus it is a matter for regret that a page should have been wasted on the use of jequirity. It is just one of those remedies that is proposed as a novelty, is employed by a few surgeons, and failing or found actually to do harm quickly falls into desuetude. We doubt whether of the younger generation of ophthalmologists one in 20 has ever employed it, and there are very few amongst the older generation who would recommend it. There are good illustrations of hyaline degeneration (or colloid of the cornea) and of the appearances presented in the band-shaped affection of the cornea. No reference is made to the subject of transplantation of the cornea.

The chapter on Diseases of the Lens is written by one of the editors (Dr. William Norris) and, as might be expected, is very complete, especially in the part dealing with the pathology of cataract, which is illustrated by numerous drawings. Dr. Norris gives many illustrations representing different forms of cataract, some sufficiently common, others like the "axial cataract" of Bach—exceedingly rare—as well as a variety of forms of zonular cataract. Dr. Norris has worked through the literature of the subject with great care. Many instructive drawings are also given of the conditions left after extraction has been performed. The operative procedures for the removal of cataract are briefly but very sensibly described. He considers that the extraction should be accomplished through a wound situated near the periphery of the cornea of moderate size and without iridectomy, unless circumstances render it advisable. He applies a light bandage for a few days only and practises in every detail great gentleness and great cleanliness. He mentions, without approving of the proceedings, the application of sutures to the wound and the washing out of the anterior chamber. In the treatment of secondary cataract no reference is made to the glaucomatous conditions which are not unfrequently excited by this apparently trifling operation and which require prompt and energetic treatment, whilst the liability to their occurrence should have been dwelt upon if only to suggest caution to the young practitioner in the adoption of this proceeding. We have no space to do more than refer to the subsequent sections which deal with the Relations of Ophthalmic Diseases to the General Affections of the System, as with Lesions of the Circulatory System, by Dr. O. Haab of Zürich, translated by Dr. William Zentmayer of Philadelphia; with Organic Diseases of the Brain and Spinal

Cord, by Mr. Henry Swanzy of Dublin; with Disorders of the Secretory and Excretory Organs, by Mr. J. B. Lawford of London; with the Acute Infectious Diseases, by Mr. John B. Story of Dublin; with Dysentery, Cholera, and Continued Fevers, by Dr. J. Santos-Fernandez of Cuba, translated by Dr. Daniel Guitéras, United States Navy; with Hysteria, by Dr. M. Parinaud of Paris, translated by Dr. Casey Wood of Chicago; with Graves's Disease and Herpes Zoster, by Mr. Jonathan Hutchinson, jun., of London; and with Functional Neurosis, by Dr. Myles Standish of Boston. The last four articles in the volume are: the Toxic Amblyopias, by Dr. George Schweinitz of Philadelphia; the Entozoa of the Human Eye, by Dr. Maximilian Salzmann of Vienna, translated by Dr. H. V. Würdemann of Milwaukee, Wisconsin, U.S.A.; Simulated Blindness, by Dr. S. Baudry of Lille, translated by Dr. Frank Marlow of Syracuse, New York, U.S.A.; and lastly, the Ocular Signs of Death, by Dr. A. Gayet of Lyons, translated by Dr. Edward Ellett of Memphis, Tennessee, U.S.A. Each of these articles constitutes a kind of monograph on the subject under consideration. Thus, in Dr. Baudry's article on Simulated Blindness no less than 60 methods of discovering it are enumerated, many, of course, being only modifications of the method by prisms, but they throw an amusing sidelight on the frequency with which loss or impairment of vision is simulated in countries where conscription is enforced. The volume is extremely well edited and is, like each of its predecessors, a valuable addition to English ophthalmic literature.

The Hæmorrhages of Pregnancy, Parturition, and the Puerperium: the Treatment of Puerperal Eclampsia by Saline Infusions, with Notes of 17 Cases. By ROBERT JARDINE, M.D. Edin. Edinburgh: W. F. Clay. 1899. Pp. 76, with two Illustrations. 8vo. Price 1*s.* 6*d.*

THESE lectures upon Hæmorrhages were given by the author at the Glasgow Maternity Hospital, while that upon Eclampsia was read before the Edinburgh Obstetrical Society. Dr. Jardine has had some experience in dealing with cases of bleeding complicating pregnancy and also in treating cases of eclampsia, and his views are therefore of interest.

In the treatment of inevitable abortion he recommends emptying the uterus in all cases as soon as possible, and he thinks that chlorate of potash is a useful drug in the treatment of cases of habitual abortion. In the cases of accidental hæmorrhage in which he examined the placenta he invariably found it degenerated. We are not told, however, what kind of degeneration was present or whether the diagnosis was confirmed by the microscope. An interesting case of accidental hæmorrhage apparently due to the use of a Champetier de Ribes's bag is reported. The bag was introduced for the purpose of inducing labour in a case of contracted pelvis and burst before it was quite full. The patient became greatly collapsed, and as in withdrawing the bag a tremendous gush of blood followed the cervix was manually dilated and the child delivered. The cervix was badly torn during the delivery of the child and the patient died two and a half hours later. Dr. Jardine is inclined to blame the bag and he says that the case contradicts the statement that no bad effect has been produced by its use. A rubber bag such as was used in this case is in no sense of the word a Champetier de Ribes's bag, one of the most important properties of which is that it is covered with silk or some similar substance and is non-elastic. If badly-made rubber bags are used such unfortunate results will, no doubt, ensue, but if a proper Champetier de Ribes's bag be employed with due precautions no such accident as happened in this case is likely to occur. The method adopted at the Rotunda Hospital of plugging the vagina in cases of external accidental hæmorrhage with the membranes unruptured is not regarded as good treatment. In cases where interference is necessary the author advises dilatation of the cervical canal and delivery, due care being taken not to lacerate the cervix. In bad cases of concealed accidental hæmorrhage Dr. Jardine is inclined to try Porro's operation.

A table of 150 cases of placenta prævia is given. Of these 40 were complete and 110 partial—viz., lateral and marginal. Of the 40 complete seven died, or 17·5 per cent., while of the 110 partial 13 died, or 11·8 per cent. In the last 100 cases only six deaths occurred. Of 153 children 91 were born dead.

Where the cervix is undilated plugging the vagina is recommended, and where the cervical canal is sufficiently dilated to admit two fingers bipolar version. The author has plugged the uterus successfully in three cases of severe post-partum hæmorrhage, and he thinks this mode of treatment preferable to the use of perchloride of iron.

Full details are given in the last chapter of 17 cases of eclampsia treated by saline injections. In most of the cases equal parts of sodium chloride and bicarbonate of potassium were used of the strength of one drachm to the pint of water. In five of the later cases acetate of soda was substituted for the potash salt. Dr. Jardine employs intracellular injection and has had no trouble at the site of injection in some 50 cases. He has lost his faith in morphia and is inclined to attribute the fatal results in two of his cases to its use. In all the cases other means of treatment besides the saline injections were employed. Five of the 17 cases ended fatally, one dying from a ruptured duodenal ulcer. Marked diuresis was set up by the saline injections. The statement that the amount of urea and uric acid eliminated was markedly increased after the injections is hardly warranted in view of the small number of the cases in which a quantitative estimation was made and in the absence of all details as to what amount and what kind of nourishment the patients were taking.

Analytical Records
FROM
THE LANCET LABORATORY.

VARIOUS SELECTED WINES.

(INNES, SMITH, AND CO., 83, HIGH-STREET, BIRMINGHAM.)

THE following wines have been selected especially, we have been informed, for medicinal use. The samples included a variety ranging from champagne, port, and claret to Australian and Hungarian wines. The analyses of the various wines resulted as follows:—Champagne Jules Delporte, Bouzzy, Reims: extractives, 3·67 per cent.; mineral matter, 0·11 per cent.; alcohol, by weight 12·38 per cent., by volume 15·30 per cent., equal to proof spirit, 26·82 per cent.; sugar, 1·92 per cent.; tartaric acid, 0·60 per cent.; and acetic acid, 0·09 per cent. This is an agreeably effervescent wine of delicate vinous character and free from excess of sugar and acidity. Though "dry" it is of a pleasant fruity character. It retains its sparkling character satisfactorily. French Red Wine No. 1: extractives, 2·56 per cent.; mineral matter, 0·24 per cent.; alcohol, by weight 9·36 per cent., by volume 11·61 per cent., equal to proof spirit 20·35 per cent.; sugar, 0·09 per cent.; tartaric acid, 0·52 per cent.; and acetic acid, 0·15 per cent. This wine is practically free from sugar and is of light alcoholic strength. It was sound in condition and possessed a delicate bouquet and taste characteristic of the esteemed wines of the Medoc district. French Red Wine No. 2: extractives, 3·05 per cent.; mineral matter, 0·21 per cent.; alcohol, by weight 11·62 per cent., by volume 14·37 per cent., equal to proof spirit 25·18 per cent.; sugar, 0·15 per cent.; tartaric acid, 0·49 per cent.; and acetic acid, 0·12 per cent. This wine is somewhat fuller than the one just described and may be

regarded as of the Burgundy type. It possesses excellent bouquet and flavour. It is free from excessive acid taste and is "smooth" and "round" to the palate. It is well adapted for restorative purposes. Hungarian Red Wine: extractives, 2·34 per cent.; mineral matter, 0·24 per cent.; alcohol, by weight 8·29 per cent., by volume 10·30 per cent., equal to proof spirit 18·04 per cent.; sugar 0·23 per cent.; tartaric acid, 0·53 per cent.; and acetic acid, 0·14 per cent. This is a characteristic wine of a quite light alcoholic strength and of delicate flavour and aroma. It is a pure wine with no additions. Australian Red Wine: extractives, 3·52 per cent.; mineral matter, 0·32 per cent.; alcohol, by weight 13·15 per cent., by volume 16·24 per cent., equal to proof spirit, 28·46 per cent.; sugar, 0·32 per cent.; tartaric acid, 0·44 per cent.; and acetic acid, 0·24 per cent. This is a typically good Australian wine, fuller bodied and containing more alcohol than the French wines described above. It is a wholesome wine and from its robust character should be useful as a recuperative taken regularly in definite quantities. Moselle No. 6: extractives, 2·14 per cent.; mineral matter, 0·18 per cent.; alcohol, by weight 8·64 per cent., by volume 10·73 per cent., equal to proof spirit 18·81 per cent.; sugar, 0·25 per cent.; tartaric acid, 0·67 per cent.; and acetic acid, 0·07 per cent. This is a high-class wine, peculiarly delicate in character both as regards flavour and bouquet. Its freedom from volatile acidity is a satisfactory feature. It is an agreeable light wine, well adapted for dietetic purposes. Portuguese Red Wine: extractives, 9·20; mineral matter, 0·22 per cent.; alcohol, by weight 17·25 per cent., by volume 21·19 per cent., equal to proof spirit 37·13 per cent.; sugar, 7·56 per cent.; tartaric acid, 0·34 per cent; and acetic acid, 0·07 per cent. This is a wine presenting the analytical features of a good port from the Alto Douro. It is fruity in character and "clean" to the palate. It is smooth to the taste and free from harsh spirit. It is a good specimen of port wine and well suited as a restorative and stimulant in special instances. Our analyses and examination of these wines show that the selection is the result of good judgment.

LONDON STOUT.

(FINDLATER, MACKIE, TODD, AND CO., FINDLATER'S CORNER, LONDON-BRIDGE, S.E.)

The results of analysis of this stout were as follows: malt extractives, 7·10 per cent.; mineral matter (alkaline phosphates), 0·25 per cent.; alcohol, by weight 4·62 per cent., by volume 5·78 per cent., equal to proof spirit 10·13 per cent. The sample was ripe yet free from excess of acidity, and possessed a mild and soft flavour. It is an excellent type of this well-known nourishing malt liquor, having the advantage of a comparatively low alcoholic strength.

CHLORETONE.

(PARKE, DAVIS, AND CO., 21, NORTH AUDLEY-STREET, GROSVENOR SQUARE, LONDON, W.)

Chloretone is an interesting compound which is formed by the interaction of chloroform, acetone, and an alkali. It is a white crystalline compound having a camphor-like odour and taste, and may be melted and sublimed at the body temperature. The sublimate occurs in white glistening needles. It burns with a greenish flame and leaves no residue. On heating with sulphuric acid a smell like formaldehyde is evolved. A solution of chloretone rapidly reduces Fehling's solution. It is, however, only slightly soluble in cold water, but is very soluble in strong alcohol, and is permanent in dilute solutions of the acids and alkalies. Chloretone appears to be a hypnotic, an analgesic, and a sedative, and is administered in tablet form, the dose being from six to 18 grains. It may also be used as a local anæsthetic in minor surgery in the same way as cocaine by the infiltration method. It has been used further with satisfactory results as a general anæsthetic in experimental physiology and pharmacology. The claims made in favour of this new hypnotic, analgesic, and anæsthetic are important and merit attention. An account of its clinical use and results is published in the Journal of the American Medical Association of Sept. 23rd, 1899.

GLUTEN BREAD AND BISCUITS.

(BONTHRON AND CO., 50 AND 52, GLASSHOUSE-STREET, REGENT-STREET, LONDON, W.)

We have received no less than 19 specimens of gluten bread and biscuits illustrating the variety of foods made especially for the requirements of the diabetic patient by the above bread and biscuit makers. We have satisfied ourselves that one and all are either free from starch or else contain a minimum quantity. We welcome the attention which has been given to this subject by Messrs. Bonthron and Co., who as the result of their labours have been able to produce an astonishing variety of diabetic foods which, while suitable physiologically for the diabetic patient, leave little to be desired on the score of palatability. Amongst the articles examined were gluten bread, gluten comfits, gluten lunch biscuits, gluten rusks, dinner-cobs, coffee biscuits, gluten charcoal (adapted for fermentative dyspepsia), almond dessert biscuits, almond drops, and others. This selection gives the physician and the patient a wide variety of foods from which to choose, and the patient will be grateful to know that while adhering to definite diet he is not bound to keep to one kind of food of which sooner or later he becomes so tired.

NEW TABLOIDS AND SOLOIDS.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

Amongst the recent tabloids added to an ever-expanding list may be mentioned the tabloid effervescent salicylic acid, containing three grains of the physiologically pure salicylic acid. The tabloid placed in water produces a briskly effervescing draught which renders the administration of salicylic acid agreeable. The specific action and uses of salicylic acid are well known in rheumatism and gout. Another interesting addition to the list of tabloids is the tabloid of potassium chloride, containing 20 grains of the salt, which is suggested for the use of gouty patients in lieu of common table salt. The potassium salts appear to offer an advantage over the sodium salts in administering to the saline treatment of gouty conditions. The tabloid admits of easily being crushed into powder at the table. We have also received specimens of the soloid potassium permanganate and alum, each soloid containing three grains of potassium permanganate and five grains of alum. The combination is a useful one, since alum preserves the permanganate in an active condition, while it acts also readily, of course, as an astringent. Under these circumstances the value of this soloid will be recognised.

OXYDOL.

(OXYDOL, LIMITED, 56, BERNERS-STREET, LONDON, W.)

According to our examination oxydol is a solution of peroxide of hydrogen which is remarkably permanent. As is well known ordinary solutions of peroxide of hydrogen soon diminish in strength until nothing but water remains. On the other hand, oxydol keeps for quite a long time, as our analyses have shown when directed upon specimens which we have kept in the laboratory some months. This is a distinct advantage since the powerful antiseptic properties of the preparation are due to peroxide of hydrogen. It has been shown that peroxide of hydrogen is useful in a wide number of applications, but chiefly as an antiseptic in contact with suppurating surfaces. The same agent has been used internally in typhoid fever, in dysentery, and in gastric disorders and infantile diarrhœa, its specific action being doubtless due to its antiseptic property or to its nascent oxygen. According to our analyses oxydol may be relied upon as a permanent and pure solution of hydrogen peroxide. The impurities found were less than 0·05 per cent. and may be referred to chlorides.

THE LANCET.

LONDON: SATURDAY, JANUARY 13, 1900.

THE recurrence of influenza in an epidemic form is a national evil of great importance. At any time such a disease constitutes a public inconvenience. Readers of Mr. DISRAELI'S letters written about the year 1837 will remember the frequency with which he alludes to the attacks of this indiscriminating foe as disabling first one distinguished person and then another. But at a crisis like the present, when every available man—and woman too—is wanted, when a strain is put on our resources of labour and skill, it is, to say the least, specially inconvenient. It is well that the public should realise this, as it rests with them largely to determine the limitations of the spread of the disease. They should realise that the medical profession is helpless in this respect. It can do much, very much, to mitigate the severity of the disease and of its principal symptoms, and not a little, if its authority be recognised, to avert its worst consequences. But to prevent its spread and its diffusion it can do little apart from the intelligent coöperation of the public.

The use of disinfectants in an amateurish and dilettante fashion is worse than useless, for it leads to a false sense of security and to the neglect of real measures of efficacy for restricting attack. The public must realise the fact that the disease is spread by persons having it, or who have recently had it, and possibly by articles that have been in contact with them in their sickness. The personal factor in the dissemination of the disease is the principal one. There is considerable doubt about the atmosphere, save that in the immediate environment of the patient, having any large share in the matter. There is much in the disease which makes it difficult for the public to act on this view. The sharp but short character of many of the cases, the absence of the requirement of notification by the State, the apparently quick return to comparative health after the short attacks, all tend to make the average patient ignore the fact that he is more or less an infected person—and he acts accordingly. He will go to his business, or his church, or his club, or his evening party—perhaps the most effective medium of all for the spread of such an infection—or hold his reception, as if nothing had happened; and, what is equally strange and true, his friends, in other respects intelligent, will go to his reception, or urge his return to business or his presence at a dance, as if he were a perfectly safe and sanitary person. Such recklessness arises from an inadequate conception of the part played by personal intercourse in the transmission of the disease. The ethics of infection are never very strong in the public mind. The selfishness of human nature is painfully assertive. As soon as the infectious patient feels within himself that his restoration to health is nigh, freedom of action is desired and no fine consideration of risk to others comes into play. If others for their part do not display selfishness enough to exclude him from their company that is their affair. This is true of far graver diseases than influenza, and of diseases the infectiousness of which has been known to all without doubt and for a very long time. But in the case of influenza the result of such carelessness is very widespread, for influenza attacks patients of all ages and, unlike most other infections, attacks them repeatedly.

We are witnessing this winter a most extensive epidemic of the disease. On the present occasion the proportion of deaths to the number of cases is not so great as in some former epidemics, but the disease has never been more typical in its manifestations—its rigors, sharp febricular pains, prostration, and depression. We do not propose in this article to go into any discussion of the scientific aspects of the disease and its treatment. Our object is to impress on our readers the advisability of making the public comprehend that it lies to a great extent in their own power to curtail the number of cases. If the sufferers are isolated, as they would be in the case of other infectious diseases, and if social intercourse is suspended till time and the proper means of disinfection have had a fair chance of rendering patients harmless to others the present rate of general infection will not be maintained. A little intelligence and common sense in individuals and households, and an early application to the medical practitioner for advice as to the prevention of fresh cases, may save many households from extreme inconvenience. It needs to be insisted on, when such heavy demands are being made on the nation at home and abroad, that to neglect proper precautions is unpatriotic as well as foolish.

IN THE LANCET of Dec. 2nd last we published a brief abstract of the important inaugural address recently delivered in London by the President of the Incorporated Society of Medical Officers of Health. Dr. NEWSHOLME, the well-known health officer of Brighton, very wisely availed himself of his accession to the presidential chair to discuss one of the most important topics which could engage the attention of a body of scientific men responsible for the safety of the public health. In his "Contribution to the Study of Epidemic Diarrhœa" Dr. NEWSHOLME has discussed a mass of information which will prove interesting and instructive to health officers everywhere, and we believe that the great labour which he has expended on the calculation and tabulation of the statistics of diarrhœa mortality, as well as in the arrangement of the numerous charts which illustrated his address, will be appreciated by the society over whose deliberations he has just been elected to preside.

In common with previous inquirers Dr. NEWSHOLME is perplexed by the absence of uniformity which characterises the nomenclature of the subject. What diseases are and what are not to be included under the head of diarrhœa is the question which demands an answer at the very outset. From the report of a special committee recently presented to the Incorporated Society of Medical Officers of Health we learn that "the classification of deaths from diarrhœa is at the present time in such a state of utter and hopeless confusion as to render the statistics of diarrhœa deaths, and consequently of zymotic death-rates, in different localities misleading and altogether useless for comparison."

This confusion would appear to be due partly to the employment by medical men of multiple names to designate the same disorder, and partly to their recently developed tendency to use the terms "enteritis" or "gastro-enteritis" in place of "diarrhœa" on the ground that the latter is the name of a symptom rather than of a disease. It is perhaps scarcely realised by certifying practitioners that by thus changing the name of a well-known disorder they are destroying the value of their certificate for the purposes of vital statistics and consequently of preventive medicine. In viewing the methods adopted at the General Register Office for ascertaining the diarrhœa mortality in the more important English towns Dr. NEWSHOLME offers some reasonable suggestions which are worthy of official notice; but he by no means fails to recognise the high value which in recent years has come to attach to the archives of Somerset House. "The returns of the Registrar-General," he says, "have been consistently compiled for a long series of years on a uniform system, and although this does not entirely eliminate errors caused by the carelessness or lack of intelligence of local registrars who contribute their returns to the central office, there can be little doubt that diarrhœal death-rates for the great towns, calculated from the Registrar-General's data, are fairly comparable in each year with one another. In this respect they differ widely from diarrhœal death-rates compiled by local medical officers of health without any exact rules to guide them." Dr. NEWSHOLME takes exception to certain of the rules laid down by the authorities at Somerset House for the guidance of local registrars in filling up returns. It would be difficult, he thinks, to justify the exclusion of deaths from enteritis, whilst admitting those from enteric catarrh as properly belonging to the diarrhœal class of disease. On this point we are unable to agree with Dr. NEWSHOLME. It occurs to us that whilst "enteric catarrh" is an indefinite and, as far as we know, unauthorised term, which finds no place in the official list of causes of death and may therefore be referred to diarrhœa without danger of confusion, "enteritis," on the contrary, is a well-defined disease, and is recognised as such by the Royal College of Physicians of London who include it in their nomenclature amongst diseases of the digestive system and thus eliminate it altogether from the zymotic group. To class as diarrhœal all deaths certified as from enteritis simply, without mention of its specific character, would, in our opinion, lead to hopeless confusion in the official returns of causes of death published by the General Register Office. Whatever be the explanation of the fact it is certain that the custom of medical practitioners in certifying deaths caused by diarrhœa has of late come to differ so widely that it is impossible for the health officer to ascertain even approximately the extent to which the disorder prevails in the district for which he is responsible. And this uncertainty will continue so long as medical men are without authoritative guidance concerning the names which should be used to distinguish this affection. We therefore regard as of hopeful omen the recent appeal of the Incorporated Society of Medical Officers of Health to the Royal College of Physicians of London for a definite judgment as to what names should be used and what names avoided by medical practitioners in certifying deaths due to epidemic diarrhœa.

Dr. NEWSHOLME, like many other experienced sanitarians, believes that increase of diarrhœa mortality is nearly related to what he calls "increasing urbanisation of the population"—that is, of course, to the overcrowding of dwellings on area, the pollution of air, soil, and water, and the various other evils which this condition implies. It i not surprising that London in the last two centuries should have suffered from diarrhœa so much more severely than it does now, for London was in those days far more urban than it is now. Its streets were narrower and there were more courts and alleys. The window-tax was in force, houses were full of effluvia from the "vaults" in the basement, and the whole soil of the city was full of organic impurities derived from both the living and the dead. "It is not difficult," remarks Dr. NEWSHOLME, "to work out points of resemblance between the state of matters in Old London and in some of our modern manufacturing towns." But it does not appear that mere density of population as such bears any constant ratio to diarrhœal mortality. The municipal borough of Brighton, for example, has a greater density than any of the other great English towns, with two exceptions, and yet there are 17 other English towns with a higher death-rate from diarrhœa. Upon one point, at any rate, experienced observers seem to be in substantial agreement, namely that epidemic diarrhœa, as a fatal disease, occurs among the labouring classes everywhere in excessive proportion. In England, by reason of our want of statistics concerning class-mortality, in which respect we are sadly behind Ireland, it is difficult to prove this, but the ordinary death returns of different parts of London, Manchester, and some other great towns clearly indicate that those districts whose social status is the lowest are the very districts which year after year experience the highest mortality from diarrhœa. After discussing the effect of high temperature combined with deficient rainfall on the prevalence of diarrhœa Dr. NEWSHOLME proceeds to summarise the results of his experience by expressing the belief that epidemic diarrhœa, like enteric fever, is a filth disease, although he recognises important points of contrast between the two diseases. He thinks that, apart from the fact that enteric fever is a disease more particularly of adults who are in the habit of taking infected food not eaten by infants, the clue to the difference of incidence of these diseases will be found in the view that the causation of diarrhœa is most closely associated with surface pollution of the *soil*, whilst enteric fever depends for its cause on less superficial pollution of the *subsoil* from leaky drains as well as from privy middens.

In treating of the etiology of epidemic diarrhœa Dr. NEWSHOLME naturally refers to the classical writings of Dr. BALLARD and especially to his preliminary report of 1888. It is to be regretted that the mass of information concerning this subject, which Dr. BALLARD collected and analysed with characteristic ability during the closing years of his life, should never have seen the light. We have it on reliable authority, however, that although Dr. BALLARD did not live to complete his final report the manuscript still exists in a forward state of preparation, and we believe that arrangements may even yet be made to preserve and publish it, if only a suitable editor could be

found who would devote the necessary time and attention to the task. We commend this matter to the consideration of the Medical Department of the Local Government Board, who are thoroughly conversant with the merits of Dr. BALLARD'S scientific work.

Finally, with regard to the immunity from diarrhœa commonly believed to be enjoyed by breast-fed children, Dr. NEWSHOLME expresses the belief, founded on local experience in Brighton, that such immunity is not so absolute as might have been expected—a fact which seems to emphasise the possibility of infection by dust, apart from food. And with respect to adult epidemic diarrhœa, which although it does not figure largely in our death returns is extremely prevalent in hot summers, Dr. NEWSHOLME thinks that much of it is similarly due to the infected dust of our city streets and alleys swallowed apart from food. Nor should the possibility of personal infection be ignored. Multiple cases in the same house he has found to be fairly common. Occasionally adults are infected by infants, sometimes the reverse. When we remember how common are secondary and tertiary cases of enteric fever in houses where unskilled nurses are employed to nurse the first patient, it is not surprising that the same should hold good for diarrhœa.

THE recent decision of the Queen's Bench Divisional Court in the case of LOGSDEN *v.* BOOTH brings within the Common Lodging Houses Acts the numerous shelters in London which since the decision of the case BOOTH *v.* FERRET have been exempt from the administration of the police and afterwards of the London County Council. This last decision is of so much importance to the sanitary administration of London and of many other communities that it deserves the attention of every person who interests himself in the welfare of the poorest class in our large cities. It was to the amelioration of the condition of this class that Lord SHAFTESBURY devoted his life, and it was due to him that the regulation of common lodging-houses has become one of the most important duties of municipal authorities. It is now nearly 50 years since the first Common Lodging Houses Act was passed and the conditions which existed before that time, and with which it was framed to deal, are personally known to but few of those who are alive at the present time. There are abundant records of these conditions, and the state of the numerous houses in which the poor and the vicious herded together without any control being exercised to prevent the grossest overcrowding or to to ensure any approximation to cleanliness should never be forgotten. The Act of 1851, however, began at once to put limitations upon these conditions, and Parliament was prepared within two years to amend a measure which was "the first successful effort that had been made to reach the very dregs of society—the first to penetrate to the deepest dens of vice, filth, and misery." The Common Lodging Houses Acts have worked well in England and have had a marked effect in raising the standard of the conditions under which the poor live. Philanthropic effort has, speaking generally, well supported the administration of the law, but philanthropic effort has in one respect struck the hardest blow against these Acts. It was argued that numerous persons existed who had not the threepence or fourpence available for the rent of a bed in a common lodging-house, that these persons had better be housed less satisfactorily than in a common lodging-house than not be housed at all, and hence have grown into existence the numerous shelters where for one penny or twopence the poor may lie down upon a mattress on the floor in close juxtaposition to each other, the ordinary requirements as to cubic space being disregarded.

We need not enter here into any discussion of the problem whether on the whole these agencies were not doing a useful work by their efforts to deal with the miserable beings who crowded into the shelters. The question which has to be considered is whether the standard of the accommodation which they provide is lower than ought to be permitted in any English community. Hitherto it has not been possible for any such standard to be fixed, for, owing to the decision of the Court of Appeal in the case of BOOTH *v.* FERRET, these shelters have not been deemed to be subject to the law relating to common lodging-houses. They were, indeed, exempted from such control by reason of their being conducted for the purposes of philanthropy and not for the purposes of profit. It is interesting to observe that when the late Lord Chief Justice gave this ruling the principal ground upon which he based his judgment was that, whereas it was necessary to protect the lodger from the desire of the keeper of the lodging-house for profit, no such protection was needed against the possible shortcomings of the philanthropist, who might be trusted to make such provision for his lodgers as was necessary without control by statute or regulation. Experience, however, has shown that "motive" is an insufficient safeguard and that the philanthropist, pressed as he no doubt is by the difficulties of finance, may take too low a view of the requirements of humanity. The decision in the case of LOGSDEN *v.* BOOTH reverses the previous decision. The present Lord Chief Justice, Mr. Justice BIGHAM, and Mr. Justice DARLING are unanimously of opinion that inasmuch as the Common Lodging Houses Acts are sanitary Acts, the fact that a house, used as a common lodging-house, is carried on for philanthropic purposes does not exempt it from the provisions of those Acts. Hence houses occupied by the poor, the rooms of which are used in common by persons strangers to each other, whether carried on for the purposes of philanthropy or of trade, must meet the requirements of the common lodging-house regulations.

This decision at once raises the question whether the standard required in common lodging-houses is to be retained or whether it is to be reduced to a level which in London would enable the small sum of twopence to provide all that is required by law. In other words, are the shelters to be improved to the level of the cheaper common lodging-houses or are the common lodging-houses to be allowed to sink to the position of shelters? This is a most important question. While undoubtedly the administration must not aim too high, the public have a right to demand that they shall be protected against the evils which may result to the community if the accommodation be of too inferior a character. The requirements of air-space and of cleanliness must be met. If these requirements be too much relaxed there will always be risk of disease, which has its

origin in overcrowding and dirt, occurring in the community. It will be interesting to observe how this problem will be solved, how the conflicting interests of finance and sanitation are to be reconciled. That there will be no hasty decision we are satisfied, for the subject must require study, but we have no reason to doubt that every effort will be made to ensure the existence of wholesome conditions in all shelters however small may be the fee the lodger pays.

IT is seldom that we have read a more interesting case as regards its clinical, pathological, and forensic features than that of Shaw and the Railway Passengers Assurance Company, which was recently submitted for decision to a tribunal of medical men, consisting of Dr. F. J. SMITH and Mr. A. J. PEPPER, representing as arbitrators respectively the claimant and the company, with Dr. MITCHELL BRUCE as umpire. For an account of the arbitration proceedings we are indebted to the *Buckingham Express* of Dec. 9th, 16th, and 23rd. JAMES SHAW, a butcher of Finmere, insured his life with the defendant company for £500. On Sept. 25th he was thrown from his cart, a wheel of which passed over his right loin. The injury he received was evidently severe, as he had to be conveyed home in a vehicle. No bones were broken, but there were symptoms of serious internal lesion from which, after a partial rally, he died in 10 weeks. He was 45 years of age and weighed between 15 and 16 stones. Both lay and professional witnesses deposed to his having enjoyed good health up to the date of his injury. He was seen by Dr. JOHN CHEESMAN shortly after the accident and was attended by him during his fatal illness. After 10 days he appeared somewhat better, but the improvement did not continue. On Oct. 19th he became rapidly worse. Dr. F. BUSZARD of Northampton, who was consulted, advised an incision to be made into a soft swelling in the pelvis, but only blood and blood-stained serum escaped. Eventually obstruction of the bowels supervened and death ensued a few days later. An inquest was held. Dr. CHEESMAN and his partner, Mr. F. DUKE, conducted the post-mortem examination. A soft mass weighing about a pound was found in the pelvis behind the peritoneum. This had no obvious attachment to the structures around, and was considered to be a blood-clot. Dr. CHEESMAN was of opinion that "the obstruction was due to a mass of blood coming from laceration of blood-vessels, caused by the accident." Mr. DUKE concluded that there had been "injury to vessels behind the kidney," and discovered "no evidence of disease anywhere."

After the inquest Mr. DUKE handed to Mr. G. H. DE'ATH, the company's local medical man, a portion of the "clot" which had been removed, and the latter gentleman gave it to Mr. WEBB, a chemist, who put it in spirit and addressed it to the Clinical Research Society of London. Mr. DE'ATH sent a telegram to Mr. J. H. TARGETT, intimating that something had been forwarded for his examination. Mr. TARGETT selected a portion of the mass and gave instructions to the assistant at the Clinical Research Laboratory to prepare a microscopical section. Only one slide was examined by Mr. TARGETT, who concluded that the substance was a sarcoma. Unfortunately the slide was not kept and the remainder of the alleged "clot" was thrown away, so that there was no chance of further investigation. Upon receipt of Mr. TARGETT'S report the insurance company very properly resisted the claim, on the ground that death was apparently due to disease and not to the injury. The policy of insurance contained what is termed an aggravation clause—i.e., a clause which held that the accident must be the proximate cause of death or that even though the accident might have accelerated death, if disease which of itself would prove fatal existed before the accident the company would not be liable. In the above case there could be no doubt that death was hastened by the accident. The arbitrators had to decide: (1) was the substance removed from the pelvis of the deceased man a blood-clot or a sarcoma? and (2) if a sarcoma did it exist prior to the accident? Dr. BUSZARD, Dr. CHEESMAN, and Mr. DUKE, the medical men who had personal knowledge of the clinical features of the case, and the two latter of whom conducted the necropsy, were firmly convinced that the mass was a blood-clot. In support of their opinion Dr. W. BULLOCH, lecturer on pathology and bacteriologist at the London Hospital, was heard. For the company Dr. WASHBOURN and Mr. PLIMMER (pathologist and bacteriologist at St. Mary's Hospital) appeared, and Mr. HERBERT PAGE and also Mr. TARGETT aided the arbitrators by their evidence.

To a non-professional person the headline in the *Buckingham Express*, "Doctors' Disagreement," would seem quite a rational presentment of the tale told by the experts on the two sides, but to a medical man and a pathologist who knows the difficulty of the subject—for medicine is not an exact science—the evidence as given on one side and the other would not appear, after all, to be utterly irreconcilable. We certainly should hesitate to affirm from the examination of one microscopical slide that a section is one of sarcomatous matter and not granulation tissue. On the assumption that the substance in the case under consideration was a sarcoma a question of vital importance to the issue at stake was, could the growth have attained the size it did in ten weeks?—i.e., could it have originated after Sept. 25th, when the man was thrown from the cart? A subsidiary question, but one of very considerable importance, also presented itself—can a sarcoma be started in a blood-clot, or in the inflammatory exudation following physical injury to the tissues? The fact that there was such divergence of opinion as to whether the mass was a clot or a new growth is sufficient warrant for the assumption of its rapid formation. We are acquainted with a case in which a recurrent sarcoma grew at the rate of more than an ounce a day, so that obviously it was possible for the mass, if a sarcoma, found by Dr. CHEESMAN and Mr. DUKE to have reached a pound in weight in ten weeks. Dr. DENNIS of New York has collected statistics which show how frequently an injury is the starting-point of a sarcomatous growth, and the conclusion is probably accepted by every medical man who has had an opportunity of studying the subject. On the whole, then, we feel justified in subscribing to the finding of the arbitration court, which was in favour of the executors of the deceased.

Annotations.

"Ne quid nimis."

MODERN BULLET-WOUNDS.

THE descriptions which have prevailed hitherto in works on surgery of the lesions inflicted by bullets must be completely rewritten. The remarkable changes of recent years in the diameter and velocity of rifle-bullets have been followed by changes equally remarkable in the wounds produced by them. A few weeks ago we described some very interesting experiments which had been performed to determine the comparative effects of modern bullets, and the results were of great value because the experiments were comparative. These experimental results had to be tried on the touchstone of actual experience, and a very interesting letter from Sir William Mac Cormac (which is published in this number of THE LANCET) shows that the practical results fall far short in severity of what might have been expected as a deduction from the experiments to which we have referred. Sir William MacCormac is particularly well qualified to express an opinion on the severity of bullet-wounds, for he had excellent opportunities of observing the lesions resulting from bullets during the Franco-Prussian War, and he tells us that in most cases the damage done by the modern bullet, especially by the Mauser, cannot be compared in severity with that inflicted by the needle-gun or the Chassepôt. The slight severity of the injury has struck him with amazement. The projectile bores a small clean hole right through the part and the aperture of exit can hardly, if at all, be distinguished from that of entrance. The wounds are on the whole aseptic and heal readily under a simple antiseptic dressing. So rapid is the healing in most cases that instances have already occurred of men who had recovered from one wound and been discharged being re-admitted later for a second bullet-wound. When only the soft parts of a limb are perforated and no important vessels have been torn the shock at the time of infliction of the injury is but slight and recovery is rapid and complete. Sir William MacCormac cites a case where a Mauser bullet traversed both thighs, passing in front of one femur and behind the other. There was very little hæmorrhage and the man was able to run another 800 yards after receiving this injury. Even when a bone has been hit the bullet may make a clean hole through it without any splintering, or with very little. This is naturally more common in the case of flat bones, such as the scapula, than in the long bones. It has also occurred in the case of the bones of the skull. In many cases even when important structures have been in the line of the bullet no harm seems to have resulted. In one instance a bullet entered on the right side of the neck immediately behind the sterno-mastoid and an inch above the clavicle, and its point of exit was in a similar position on the other side. Some difficulty in swallowing and speaking followed, but this passed off almost completely in a very short time. In another case the shot passed through the left ilium just below the crest and emerged a little more than an inch below the ensiform cartilage. From the situation of the apertures of entrance and exit, and remembering that a Mauser bullet passes straight from one to the other, turning neither to the right hand nor to the left, we are justified in thinking that the bullet must have pierced the stomach, but no symptoms of any such injury appeared. The patient took his food from the beginning without any inconvenience and had a rapid and uneventful convalescence. In yet another instance, from the situation of the wounds and from the fact that a most obstinate constipation followed the injury, it is almost certain that the colon was perforated, yet no peritonitis arose. Not the least remarkable of the effects of the Mauser bullet is the very slight hæmorrhage resulting from perforation of the lung. There is generally a little hæmoptysis which soon ceases and convalescence ensues. Even when a comminuted fracture of a bone of a limb has been produced complete consolidation of the broken bone may result, though the fracture was necessarily compound. A striking case of perforation of a joint shows that only a slight synovitis may follow. This is in marked contrast to the havoc produced by a large-bore bullet. These results must produce a feeling of hopefulness in the treatment of modern bullet-wounds, for they show that in many cases a temporary interference with military service is all that is produced. To Sir William Mac Cormac the profession owes a deep debt of gratitude for his graphic pictures written from the seat of war. While helping his country he is at the same time making a solid contribution to our scientific knowledge.

MALARIA AND MOSQUITOES.

WE would draw the attention of those of our readers who are interested in the investigations which have been carried on by various observers as to the relation alleged to exist between malaria and mosquitoes to a paper by Dr. G. Bastianelli and Dr. A. Bignami published in this issue. We owe the translation of this paper into English to Dr. G. Sandison Brock. An excellent *résumé* is given of the present state of the question, which will be understood not only by those who have followed the accounts which have appeared from time to time in medical literature of the researches which have been conducted in malarious districts, but also by those who are not acquainted with the work already accomplished. Due credit is given to other observers. The æstivo-autumnal parasites are first considered and a sketch is given of the two life-cycles which they present, one of which is completed entirely in man and is the cause of the fever, while the other is only initiated in man and is completed in mosquitoes of the genus anopheles. All three species of malarial parasite, distinguishable with certainty from each other, adopt as host the same species of mosquito, and the authors of the paper proceed to discuss whether the parasites preserve intact the distinguishing characters of their species. An affirmative answer is returned to this question, relying not merely on morphological data, but also on the results of experiment, and it is shown how even after their passage through the anopheles the species of malarial parasite remain distinct and do not become transformed one into another. Further, it is affirmed that a single infected mosquito is capable of inoculating malaria into man, and even more, namely, that a single mosquito by successive bites can infect several people. It sometimes happens that two species of parasite may develop in one and the same mosquito—for instance, an æstival and a tertian parasite—the two remaining distinct, so that it can well happen that a single anopheles may inoculate a mixed infection. The combination of the two fevers is by no means rare in Italy. The knowledge of these facts is of considerable practical importance. It has been suggested that much may be done to mitigate the prevalence of malaria in a district by destroying the breeding places of the anopheles, but the above facts indicate how thoroughly that would have to be done in order to make any appreciable effect in the occurrence of the disease. The concluding paragraphs of the paper are particularly worthy of attention, for they refer to the measures of prophylaxis which should be taken against infection. It is insisted that the careful treatment of the malarial patient constitutes one of the principal tasks of

social hygiene. The authors maintain that the energetic treatment with quinine from the commencement of the infection of the æstival fevers not only reduces the danger of relapses to a minimum, but has a great importance for general prophylaxis, since the parasites by its means can be prevented from developing into those forms which continue their life in the anopheles. The treatment of the malarial patient ought, therefore, to be carried out systematically and energetically in the same manner as is practised when countries are invaded by other epidemic and contagious diseases.

ACQUIRED COLOUR-BLINDNESS.

IN the December number of the *Scottish Medical and Surgical Journal* Dr. George Mackay and Dr. J. C. Dunlop of Edinburgh publish a full description of the cerebral lesions observed in an instance of complete acquired colour-blindness, achromatic vision being at the same time retained. They believe this to be the first complete case of the kind that has been submitted to post-mortem examination. Verrey[1] has recorded a comparable case of acquired one-sided colour-blindness (hemiachromatopsia) examined post mortem. The patient in the present instance was aged 62 years, was a man of great mental capacity, and his colour-sense had always been good. He took a great interest in his garden and was able to appreciate the most delicate colours in flowers. In 1896 his health began to fail and he became anæmic. An affection of the sight was first noticed on Nov. 24th, 1897. On the previous day his eyesight had been as usual, but on the morning of the 24th he found himself unable to read his letters, and when out walking later in the day he was unable to recognise vivid colours in some children's dresses. On Dec. 23rd, 1897, he was examined by Dr. Dunlop and found to be completely colour-blind. All coloured objects appeared to be grey. He could not tell by sight whether a fire in the grate of his room was glowing or not. His distant form sense, as tested by Snellen's types, seemed good. On Jan. 26th, 1898, notes of his condition were made to the effect that the external aspect of his eyes was natural, there were no obvious signs of blindness, he recognised faces, and walked about freely. The pupils were of medium size, equal, reacting to light and on convergence. The optic discs were slightly senile and anæmic, but not atrophic. The fundus generally was healthy; the refraction was emmetropic. V.=$\frac{6}{12}$ Sn. with each eye separately. The colour sense was completely suppressed for all colours all over the fields, every colour appearing to be grey. The patient's intellect was clear, he had no word blindness, his memory of colours seemed good, and he was quite conscious of his lost sense. The diagnosis was double homonymous hemianopsia, complete for colour sense, incomplete for form sense about the point of fixation, probably due to symmetrical cortical lesions in or near the calcarine fissures, with perhaps slightly more extensive destruction of the right cerebral visual area than of the left. During the two months following this examination he acquired greater facility in reading, but there was no restoration of his colour sense. On April 17th he suddenly developed a right-sided hemiplegia and on April 22nd he died. Six illustrations of the cerebral lesions accompany the memoir, and the description of them is too long for quotation in full, but is summed up as follows: An atrophy of the posterior part of the temporo-occipital convolution on both sides, that on the right side having caused a greater destruction of tissue than that of the left side, but the atrophy of the left side had extended rather deeper than that of the right, having reached the floor of the lateral ventricle and a small portion of the grey substance of the calcarine fissure. On both sides the lower edge of the optic radiation was affected. The nature of the atrophy was found to be due to a hyaline degeneration of the adventitia of the vessels which had to a great extent cut off the blood-supply and had led to complete destruction of the proper nerve elements, both fibres and cells, of the affected portions of the brain. Dr. Mackay and Dr. Dunlop remark that in this case the total loss of colour sense was associated with a bilateral lesion of the fusiform convolution so well defined and symmetrical that it becomes difficult to avoid the conclusion that the grey matter of that convolution is probably concerned in the perception of colours.

THE ELECTRIC CURRENT AS A CAUSE OF FIRE.

WE commented upon this subject in THE LANCET of Dec. 23rd (p. 1753), since which time a great deal of correspondence has appeared in the *Times*, and we have ourselves received communications upon the subject from electrical experts. It will be remembered that the origin of the discussion was an outbreak of fire which occurred in a domestic dwelling through evident defects in the system of wiring. It would appear that considerable controversy amongst electrical engineers has been held for some years as to the best and safest means of "wiring" houses. There can be little doubt that the best method would be to enclose the "leads" in pipes and thus absolutely prevent leakage. We have received pamphlets written by Mr. F. Bathurst, A.I.E.E., in which this method is urged as economical, efficient, and safe. Common gas barrel seems suitable for the purpose, but it must be carefully lined with some insulating material. Probably this procedure would add much to the expense of installation, but in view of the increasing number of accidents it would seem that something better must be adopted than wooden cases. Besides, there is a tendency on the part of electric-supply companies to increase the voltage on the services. This fact adds a very strong argument in favour of enclosing electric wires in pipes.

THE LATE SIR JAMES PAGET

AS we announced in our issue of Jan. 6th, the first part of the burial service for the late Sir James Paget was said in Westminster Abbey on Jan. 4th. Her Majesty the Queen, who was represented by Captain Phillips, Gentleman Usher, and Dr. T. Barlow, physician to the Royal Household, sent a wreath to which was attached a card inscribed, "A token of respect and esteem. Victoria R.I." The pall-bearers were Lord Lister, representing the Royal Society; Sir Trevor Lawrence and Sir Thomas Smith, representing St. Bartholomew's Hospital; Dr. Pye-Smith, the Senior Censor, representing the Royal College of Physicians of London in the unavoidable absence through illness of the President, Dr. W. S. Church. The Royal College of Surgeons of England was represented by Mr. H. G. Howse, Vice-President, and Mr. T. Bryant. The President, Sir William Mac Cormac, was, of course, unable to be present owing to his being at the seat of war in South Africa. Dr. Ince, the Regius Professor of Divinity, represented the University of Oxford and Sir Michael Foster represented the University of Cambridge. The principal mourners were Sir James Paget's sons and daughters, his nurse (Miss Finn), and one or two others. Professor A. R. Simpson came from Edinburgh as representative of the University. Dr. M. Beverley and Mr. H. A. Ballance attended as representing the staff of the Norfolk and Norwich Hospital and Dr. W. A. Elliston of Ipswich, the President-elect, attended as representing the British Medical Association. The body was interred at Finchley

Cemetery, where Dr. Francis Paget, Dean of Christ Church, Oxford, said the committal portion of the office. A large number of medical and other scientific men were present in the Abbey. A funeral is always an impressive sight and perhaps never more so than in the case of a medical man who has all his life fought a foe to whom he knows that he must one day himself succumb. The Abbey Church of St. Peter at Westminster has seen the obsequies of many famous men, but among medical men of few greater than James Paget since the day when the remains of Hunter were translated from the vaults of St. Martin-in-the-Fields.

STREET NOISES.

THE Birmingham magistrates held a meeting on Jan. 3rd at which among other subjects the powers of the city to deal with the nuisance of yelling newsboys were considered. Sir James Sawyer considered that the nuisance called for repression. Mr. Barradale said that there was a by-law dealingwith the matter, but that it was recently held by the Court of Queen's Bench that somebody must support the police and show that some passer-by or inhabitant was annoyed. The Chief Constable said that he was quite aware of the nuisance and had issued special orders but that it was very hard to catch the boys. He considered that new legislation was required. Sir James Sawyer related how he had entrapped five boys in half an hour. Birmingham may safely be left to deal with her own nuisances, but we must say that we should like to see the London County Council or the new municipalities created by the London Government Act do something in the matter. The County Council seem to consider themselves powerless. If, however, they can, as they have done, enlist the services of the police to arrest or deal with citizens whose dogs are not properly labeled, they could also enlist the police to stop newsboys who yell.

BACTERIOLOGY OF TYPHUS FEVER.

IN THE LANCET of Feb. 11th, 1899 (page 390), it was mentioned that Dr. Andrew Balfour and Dr. Charles Porter of Edinburgh had found a diplococcus in the blood in 19 cases of typhus fever examined during life and in seven cases examined post mortem. Since that time these gentlemen have much extended their research, and the December number of the *Edinburgh Medical Journal* contains a long article giving the results obtained by them in 43 cases of the disease in question, both in the acute and convalescent stages, and in 12 cases post mortem. In 40 cases the blood was taken while the fever was acute, ranging from the second to the fifteenth day; three cases were examined only after convalescence was well advanced. In 36 out of the 43—i.e., in about 88 per cent.—a diplococcus was found 1 μ in breadth and about 2 μ long. It was non-capsulated, non-motile, and did not possess flagella. It had, however, a marked oscillatory movement and could frequently be seen turning over and over in its long axis both in ordinary and hanging-drop preparations. It stained well with carbol-fuchsin, gentian-violet, and retained the stain in Gram's method. In cultivation experiments it was found that no growth took place when the blood was transferred directly to solid media, even when the surface of the medium was moistened with bouillon. Broth became cloudy but tended to clear by deposit. The deposit was greyish-white in colour when unmixed with precipitated blood. There was no pellicle and no odour was detected. On agar the growth was rapid and copious and had the appearance of a white streak. There was no gas-formation in glucose jelly. Milk was coagulated in 48 hours. Litmus broth showed acid reaction within 24 hours. The most favourable temperature for the growth of the organism appeared to be 37° C. In stab cultures growth occurred as a continuous streak or as small dots, was confined to the line of inoculation, and liquefaction took place from above downwards. Strange to say, the same organism was found in 40 out of 46 cases of enteric fever which were examined. Of the 12 typhus fever cases examined post mortem all but one yielded a diplococcus which by plate cultivation was isolated in nine out of the 11 cases. Microscopically and in culture it seemed to be the same as that obtained in the living blood, the only difference being that its growth on agar-jelly, and potato was, except in one case, pigmented. The streak was white or faint cream at first, but in the course of a few days gradually assumed a distinct orange yellow. The growth on blood serum was always white. Eight rabbits were inoculated with cultures of the diplococcus obtained from the living blood; with seven of them very little effect was produced; the eighth became ill next day and was in a dying state on the thirty-first day, when it was killed and typical diplococci were discovered in cultures made from its blood. 11 inoculations of rabbits were made with the post-mortem diplococcus; three of these were intravenous and proved rapidly fatal; the typical diplococcus was obtained after death. Inoculation of three monkeys and two guinea-pigs gave negative results. A fourth monkey inoculated with a culture of the diplococcus obtained from a typhus fever patient post mortem was unwell for about a fortnight, after which it regained its normal appearance; typical diplococci were cultivated from its blood. A fifth monkey was inoculated with a culture of the post-mortem diplococcus and was slightly ill for about a week but gradually recovered. Its blood yielded a culture of the diplococcus, and it was remarkable that whereas an organism with a pigmented growth on agar was injected that which was recovered gave a white growth exactly resembling the culture of the diplococcus obtained from the living blood of the typhus patients. The organisms obtained post mortem from the typhus patients appeared to be almost identical with that derived from the living blood, the only difference between them being that while the latter is apparently non-pathogenic and non-pigmented the former is pigmented and is moreover pathogenic, at least to rabbits.

OBEY YOUR MEDICAL MAN.

THERE recently passed away at Bromsgrove Mr. Henry Swinson, M.R.C.S. Eng., in his hundredth year. Soon after qualifying (he became a Member of the Royal College of Surgeons of England in 1825) he had an attack of hæmoptysis, and his medical advisers warned him that only by complete rest and freedom from exertion could he manage to maintain his health. He followed this advice with marked success, led a regular, placid life, and took walking exercise every day. Up to the last few months he was accustomed to walk from his house into Bromsgrove and back, a distance in all of three miles, almost daily. We have cited the case of Mr. Swinson as an instance of the advantages to be gained in certain ways by strictly following out the advice of a medical attendant. On the other hand, patients who have been doomed by their advisers have not only falsified the prediction but have done useful and honourable work. In our own profession there is the leading case of the late Sir Andrew Clark, who was elected to the staff of the London Hospital in 1854 with the remark from the medical staff of "Let Clark have it; he is only a poor Scotsman and has not long to live." Yet Clark lived until 1893 and saw all his colleagues at the time of his election pre-decease him. In another field we may recall the instance of Dr. Martin Joseph Routh, who was President of Magdalen College, Oxford, for 63 years, who died in his hundredth year, and who was the last Head of a House who habitually wore an official wig. The Oxford tradition is that Routh was elected President with an idea

that he would not live very long. This expectation was not fulfilled and if it had been the world would have been the poorer. Though we do not mean that it is always necessary to continue to obey one precept throughout a period of 75 years, yet it is right to remember that it is but little use to consult a medical man except with the intention of obeying him and to no class of men is this advice applicable more than to medical men themselves. The late Mr. Swinson's longevity forms a remarkable example of the value of obeying the medical man.

THE UNIVERSITY OF LONDON: THE NEXT MEETING OF CONVOCATION.

THE next meeting of the graduates who are members of Convocation will be held at Burlington-gardens on Monday next, Jan. 15th, at 5 P.M. An especial interest is attached to the meeting as it is possible that it will be the last meeting of Convocation in the present building and that the University will have taken up its abode at the Imperial Institute before Convocation reassembles in May. The new statutes, which are nearly complete, may be laid before Parliament in the next session. If this be so Convocation will have the duty in May of appointing its representatives on the Senate of the re-constructed University. They will be 16 in number in addition to the Chancellor of the University and the Chairman of Convocation, and eight of the 16 will retire every two years. The graduates will vote separately in the different faculties on signed voting papers. Many graduates have paid but little attention to the affairs of the existing University and are therefore not members of Convocation. If they wish to manifest increasing interest in the re-constituted University and to vote at the next senatorial election, their names, with a life composition fee of £1, or a yearly subscription of 5*s*., must be sent to the Registrar of the University not later than to-day (Jan. 13th).

PAROTITIS FROM PLUMBISM.

AT the meeting of the Société Médicale des Hôpitaux of Paris on Dec. 8th M. André Petit and M. Hudelo read papers on Saturnine Parotitis—a condition which, though evidently well recognised by French writers, does not appear to have received attention in this country. In 1882 Comby described hypertrophy of the parotid glands in plumbism, and cases of parotid affection were brought before the society by Achard in 1896 and by Launois in 1897. Claisse and Dupré published an interesting study of the subject in the *Presse Médicale* for December, 1897. Further parotitis has been described in other intoxications—in copper by Chauffard and, more often, in iodide of potassium intoxication by Comby, Villard, Regnier, Balzer, Renault, and Salmon. M. Petit presented to the society a painter, aged 30 years, who first showed symptoms of plumbism in 1889, in the form of colic of which he had 11 attacks. In July, 1898, he had right radial paralysis from which he recovered in three months. In November, 1899, during an attack of colic the parotid regions became painful and swollen and five or six days later right radial paralysis again appeared. The patient presented himself at hospital on the fourth day when the parotid glands were found to be markedly swollen and tender. The overlying skin was normal. There was a blue line on the gums. M. Hudelo related a case in which acute unilateral supervened on chronic bilateral parotitis. A painter, aged 31 years, who had had several attacks of colic and who was suffering from extensor paralysis of the left hand, entered hospital on Nov. 10th, 1899. In February he began to feel pain in the parotid regions which was accompanied by some trismus but not by any swelling. A blue line was present on the gums. The parotid glands were swollen. On Nov. 14th he complained of acute pain in the right parotid region and the gland formed a projection of the size of a hazel nut, which on the 15th was of the size of a small walnut and on the 16th of half of an orange. The skin was tense and red and the temperature was 102·2° F. On the 18th the temperature had fallen to normal and the pain and swelling were much diminished. On the 20th the condition was normal. The mouth could then be minutely examined. Stenon's duct on the right side was indurated and at its orifice the mucous membrane was tumefied, blackish, and ulcerated. Under iodide of potassium the chronic enlargement of the parotid glands quickly disappeared. Two theories of saturnine parotitis have been brought forward—that it is due to irritation by the lead in process of excretion by the saliva, and that it is due to a superadded infection of buccal origin. In the second case the latter theory seems to be the more probable; in the first lead was found in the saliva.

THE BELLADONNA PLASTER CONTROVERSY.

SOME time ago a very interesting inquiry was undertaken with the view of ascertaining how far belladonna plasters complied with the requirements of the British Pharmacopœia. The results were not satisfactory, few of the plasters yielding on analysis the required one-half per cent. of belladonna alkaloid. Since this inquiry certain manufacturers have taken exception to the results because, first, they hold that the samples should have been compared with the standard of the United States Pharmacopœia which, however, appears to be very indefinite on this question. Secondly, a charge of inaccuracy was brought based upon the circumstance that the reports of different analysts varied as regards the quantity of total alkaloids contained in samples bearing the same numbers. Thirdly, it is stated that it was a gross error on the part of some of the analysts that they identified the alkaloids of scopolia carniolica as tropeines. Accordingly a new inquiry was undertaken and the results were published recently in a bulletin issued from the laboratory of the Inland Revenue Department by the Canadian Government. These results are not essentially different from those previously exhibited. The whole controversy should lead to a more definite requirement on the part of the United States Pharmacopœia in regard to the standard of alkaloidal strength of belladonna plasters.

COMPLIMENTARY DINNER TO MR. WATSON CHEYNE AND MR. G. LENTHAL CHEATLE.

ON Thursday, Jan. 4th, in the Whitehall Rooms of the Hôtel Métropole, a complimentary dinner was given to Mr. Watson Cheyne and Mr. G. Lenthal Cheatle on the occasion of their departure for South Africa. The assembly included members of the Council and of the Hospital Committee of King's College, and old and past and present students of the school, among those present being Professor A. Hughes (the chairman), Dr. W. D. Halliburton, Dr. Playfair, Dr. Burney Yeo, Dr. Crookshank, Mr. C. E. Layton, Mr. George W. Bell, Mr. C. Caudry, Rev. Dr. Ware, Mr. A. H. Morton, Mr. W. Rose, Dr. Curnow, Dr. N. Tirard, Mr. F. Lee, Captain V. Mathews, Dr. F. Willcocks, Mr. A. Carless, Dr. Urban Pritchard, Dr. Dawson Williams, Mr. P. T. Beale, Sir Hugh Beevor, Dr. W. A. Turner, Mr. L. V. Cargill, Mr. M. M. McHardy, and Mr. A. S. Underwood. The toast of "The Queen," proposed by the chairman, was most enthusiastically honoured, while the toast of "The Army, Navy, and Reserve Forces," also proposed by the chairman and responded to by Captain V. Mathews, was patriotically received. The toast of "The Guests of the Evening" called forth from Mr. Watson Cheyne and Mr. Cheatle words of thanks for the honour which had been

done them by their hospital. The Rev. Dr. Robertson proposed "King's College Hospital," to which Dr. Burney Yeo replied. During the course of the evening the two guests were chaired round the room by the students who afterwards called upon Mr. Cheyne to add to the musical portion of the programme, to which he responded by singing "Annie Laurie." On Saturday, Jan. 6th, the friends of Mr. Cheyne and Mr. Cheatle assembled at Waterloo Station to wish them God-speed and a safe return. The students of the hospital were there also and testified their affection and esteem for their departing teachers with no uncertain voice.

A VIEW OF SANITARY PROGRESS IN 1899.

OF the multitude of important public subjects which demand attention none, perhaps, appeal less to the notice of the average man than the vital ones of sewerage and water-supply. In passing through the streets of his native town when his progress is barred by the excavator he may murmur a few uncomplimentary remarks relative to the authorities having caused him some personal inconvenience, or, if a householder, the prospective addition of an extra shilling on the rates may add to the interest of the occasion; but as to constructive details, management of, or the final disposal of, the sewage, the average man is supremely ignorant and indifferent. All those of us, however, whose duty or inclination directs attention to these questions must have noticed that the year that has just passed has been one of exceptional activity throughout the country both in relation to water-supply and to questions of sewerage. Progress has been from time to time reported as to the practical inquiries of the Royal Commission on the Disposal and Treatment of Sewage, but the task of practical investigation is so great that it would be idle to expect the report to appear before some time has elapsed, but the mere taking of evidence has directed the minds of thinking men to the subject. The inducements held out in favour of recent methods introduced to assist in the disposal of sewage by bacterial agency have stimulated bewildered county councillors to borrow, often vast sums of money, for sewerage works, hoping thereby to escape from an incubus which grows yearly more insupportable. The ultimate results of these contracted debts, which frequently seem to be enormous in comparison to the individual populations, it is difficult to forecast, but judging by past experience it is to be feared that the works undertaken will not continue in a state of efficiency to the end of the term for which the loans have been advanced without very considerable future outlay. Another difficulty has been the increased demands for water made by growing population largely owing to the introduction of water-carriage as a means to sewage disposal. This and the wholesale pollution of our rivers and streams by the wastes from factories and by raw or inefficiently treated domestic sewage has driven local authorities to seek in districts remote from human habitation those pure supplies which, but for the previous neglect of all sanitary laws, would be by their own doors. To attempt to enumerate a tithe of the work at present contemplated or in hand would yield a list of formidable proportions, but our readers will readily recall the names of some of the many important works in progress. Whether the present rush by rural communities towards the water-carriage system, in imitation of our large towns, is a wise course and the true solution of their sewerage problem is perhaps questionable. Many whose opinions are worthy of very careful consideration by reason of the study devoted by them to this subject do not believe that this system of water-carriage is the "be all and end all" of a great question, as its votaries would have us to believe, for it is by no means difficult to conceive districts and conditions where such a system is undesirable. County councils are awkwardly placed as to obtaining independent information upon any other system, as the advice most easily available is from sources devoted entirely to the one so universally adopted. In this matter it is to be hoped that the inquiries of the Royal Commission on the Disposal and Treatment of Sewage will be of great assistance. It does not follow that because in some instances a dry system of collection and disposal has not been attended with brilliant success some such system may not yet be found infinitely preferable to one of water-carriage. Recent research has added largely to our knowledge of this subject, and many objections that previously seemed fatal to success have been removed.

DENTAL APPOINTMENTS AT GENERAL HOSPITALS.

IN THE LANCET of Dec. 23rd, 1899 (p. 1749) we published an annotation upon the above subject and in the two following issues, of Dec. 30th, 1899, and of Jan. 6th, 1900 (pp. 1858 and 62), letters appeared from correspondents who were interested in the matter. Generally the opinion seemed to be that where a medical school was attached so that the dental surgeon had to act in a teaching capacity as well as in a purely professional one, then he should possess a medical qualification as well as one in dental surgery. We have received a copy of a petition to the board of management of the London Hospital. The petition is signed by past and present dental surgeons, all of whom also possess medical qualifications, of the 12 great metropolitan hospitals having medical schools attached, and it approaches the board with a request that it may be made compulsory "at your institution for all candidates for the post of dental surgeon to be registered on both the Dental and Medical Registers." The petitioners further state that they are unanimously of opinion that dental surgeons whose duty it is to teach medical students or practitioners shall have received at least the additional medical education implied in the conjoint diplomas. They conclude by stating that "something more is necessary in the person of a teacher at a hospital than that he shall have passed the ordinary pass examination that entitles him to practise." We need not recapitulate the arguments that we have so recently set forth upon this subject, but will only express a hope that the two metropolitan hospitals which at present consider it sufficient for their dental surgeons to possess only a dental degree will reconsider their position.

SPLENIC ANÆMIA.

THE *American Journal of the Medical Sciences* for October contains an important article by Dr. B. W. Sippy on Splenic Anæmia, a disease of which but a very limited number of cases have been recorded and which has only recently attracted much attention. A man, aged 45 years, went to hospital. He had always enjoyed good health until three and a half years previously when he noticed a swelling in the left hypochondrium and became easily fatigued and short of breath. He complained of slight nausea, vomited occasionally, lost appetite, and suffered from diarrhœa. Then he became rather constipated and had chilly sensations now and then, followed by fever. Epistaxis began two years previously and often recurred. The feet became swollen a month previously to examination. The tumour in the left side gradually grew. He lost about 25 lb. in weight and could walk only a short distance without experiencing fatigue and dyspnœa. There was a slight sub-icteric hue of the skin and conjunctivæ. The mucous membranes were pale. The inguinal glands were slightly enlarged. The lower limbs were œdematous to within a few inches of the knees. There was slight œdema of both wrists. The spleen was greatly enlarged, extending to within three fingers' breadth of the pubes. The liver was enlarged, extending to

within one and a half inches of the umbilicus. Splenic leukæmia was diagnosed, but examination of the blood showed that the diagnosis was not correct. There were 1,740,000 red and 5214 white corpuscles per cubic millimetre; the hæmoglobin was 30 per cent. The leucocytes showed the following relations: polynuclear neutrophiles, 66·4 per cent.; eosinophile, 10·8 per cent.; transitional forms, 3 per cent.; large mononuclear, 4 per cent.; and small mononuclear or lymphocytes, 25 per cent. Splenic anæmia was therefore diagnosed. The patient was kept in bed and iron, arsenic, and bitter tonics were given. Pallor and œdema gradually increased and ascites appeared. Death took place at the end of four months. At the necropsy the spleen weighed 5·2 lb. The section was red, firm, and uniform. Microscopically the reticulum of some of the Malpighian corpuscles was increased and a few showed considerable sclerosis. The liver weighed 6·2 lb.; there were slight increase of the interlobular connective tissue and marked infiltration of lymphoid elements. Splenic anæmia shares in the general obscurity surrounding the allied disease of leukæmia and the other varieties of pseudo-leukæmia. The splenic enlargement appears to be the primary change and the anæmia secondary, for the former in all the reported cases has preceded the latter, in some for a period of a year. Moreover, recovery has taken place in five cases after splenectomy. Medical treatment appears quite unable to arrest the fatal progress of the disease.

TREATMENT OF GRAVES'S DISEASE.

IT is notorious that hitherto the treatment of this disease has been most unsatisfactory. The way is open for any therapeutical suggestion on the subject and we gladly notice a paper to be found in the *New York Medical Record* of Dec. 2nd, 1899, by Charles L. Minor, M.D., Ashville, N.C Dr. Minor entitles his paper "Two Cases of Graves's Disease successfully treated as Intestinal Auto-intoxications." It was read before the Mississippi Valley Medical Association in Chicago. After an interesting allusion to the two theories of the origin of this disease—the neurogenic and the thyrogenic and inclining to the latter theory—he gives the details of two cases treated, and in one case, if not in both, safely cured on the theory that the disease has its origin, in some cases at least, in an intestinal auto-intoxication. Dr. Minor in a footnote alludes to Dr. C. M. Allan's case of Graves's disease following influenza which was much benefited by the administration of large quantities of bile (pig's, in the form of Burroughs and Wellcome's tabloids).[1] Dr. Minor's first case was a fairly typical one. The patient was a young woman, aged 22 years, and she was not neurotic. Her childhood was healthy save for frequent attacks of tonsillitis. In her seventeenth year she had typhoid fever, with no sequelæ; also ague of tertian type. Prior to 1893 her digestion was good, though she was subject to constipation and her appetite was capricious. In 1893 she went, on account of malarial attacks, to Massanetta Springs where she began to suffer acute attacks of indigestion with violent pain in the lower abdomen about two hours after meals, not accompanied with diarrhœa, and generally traceable to indiscretions of diet, favoured by the patient's tastes and the style of living in her home where over-rich and highly-seasoned dishes were the rule. After much social over-exertion in 1895 she developed a very typical chlorosis. In the autumn of 1896 a rapid heart action, apparently the result of much exercise, was noted. In January, 1897, the diagnosis of Graves's disease was made and she went in February of that year under the care of Dr. Osler. All the ordinary remedies were tried without effect. In May she came under Dr. Minor's care, with a pulse of 130, nervous irritability, symptoms of intestinal fermentation with over-distended intestines, thyroid visibly enlarged, especially on the left side, and a moderate degree of exophthalmos. After failure with ordinary remedies Dr. Minor acted on the theory of the intestinal origin of the disease. He ordered a strictly regulated diet—the exclusion of all sugars, careful limitation of starches, a few simple green vegetables, such as "squash" and spinach, with underdone meats or chicken. Tea, coffee, hot breads, made dishes, condiments, and candy were all stopped. Meals at regular hours, with quiet and repose, but not rest in bed, were ordered. Lactate or albuminate of iron was given, with anti-fermentative mixtures, such as salol, resorcin, beta-naphthol, and guaiacol carbonate, not forgetting an occasional dose of calomel. But the chief remedy against intestinal fermentation was intestinal lavage with hot water (from 100° to 105° F.), allowing from one quart to a gallon of water to flow slowly into the rectum till the whole colon was full. This was at first used nightly, then at longer and longer intervals, and was not finally abandoned for about a year. In about six weeks all the principal symptoms were improved. Dietetic indiscretions were invariably followed by a return of the symptoms. By June, 1898, she was completely restored, and in October, 1899, reported herself completely well, with a pulse of 80, and able to ride a bicycle for 25 or 30 miles. In the second case, that of a married woman, a fast eater and a gourmand, similar treatment was equally effective. She remains well at the end of two years. Of course, we cannot generalise on the strength of two cases, but they are full of suggestion, and the profession will soon determine its applicability to the average cases of this disease.

[1] THE LANCET, August 26th, 1899, p. 555, &c.

THE UNIVERSITY OF LONDON: ITS REPRESENTATION IN PARLIAMENT.

NO one demurs at the proposition that the medical degree of the University of London as at present constituted marks its possessor as a finished physician as far as the discrimination of examiners and the scope of written and oral cross-examinations can form tests of knowledge. The University has upon its roll of graduates a long list of first-class medical men and a considerable list of eminent ones, so that it is particularly a constituency which might be expected to send to Parliament a medical man. All who follow public affairs must see that medical questions, or, at any rate, questions with a distinct medical side to them, bulk largely in the affairs of the country, yet the medical profession is but poorly represented in the councils of the country. In the House of Lords we have but one peer and in the House of Commons a mere handful of members. We say this without detracting from the merits of the present medical members of Parliament, who are good men individually but too small a body collectively to make much impression upon their fellows. The elevation of Sir John Lubbock to the peerage, a well-earned honour which has long been expected for him, gives the University of London an opportunity of sending a new member to the House of Commons, and medical men everywhere will feel as we do—that a medical man should be selected, if only because of the high medical position which the graduates of the University hold. Two candidates are before the constituency already—Dr. Busk, the Chairman of Convocation, and Dr. W. J. Collins, a late Chairman of the London County Council. Dr. Busk is a commissioner under the London University Commission Act, and therefore has the constitution of the reorganised university at his fingers' tips, while his public record shows him to be a man of the highest general and legal attainments. But in our opinion what may be called the domestic side of London University requires no

voice in Parliament, while St. Stephen's has certainly little need of further legal acumen. Dr. Collins, as a medical graduate with a good scientific position and record and as a public man who has exhibited in his capacity of chairman of the London County Council tact, judgment, and administrative skill, is certainly a strong candidate, but we do not consider that he possesses exactly the qualifications to fit him to sit in the House of Commons in succession to Robert Lowe (Lord Sherbrooke) and Sir John Lubbock as representative of London University. As is well known he is at variance with accepted scientific belief on the question of vaccination. Whether he is or is not opposed *in toto* to vaccination or whether it is only compulsory processes of inoculation that are distasteful to him is beside the point. The general feeling among medical men that the University of London ought to be represented by a medical man surely implies that the Member of Parliament for the University should be an embodied expression of the highest medical opinion. This is what Dr. Collins—an exceedingly clever man, a tried administrator, and an earnest worker in the cause of medicine and public health—is not; and the objection is a serious one.

THE QUANTITATIVE ESTIMATION OF SMALL QUANTITIES OF MERCURY IN URINE.

IT is often desirable to be able to determine the exact quantity of mercury in urine, as when mercury is being administered medicinally or in toxicological practice. We publish this week a somewhat lengthy description of a method which has been devised by its authors with, as they state, both speed and accuracy in view. The method depends upon the fact that stannous chloride when added to solutions of mercury salts reduces them to metallic mercury in a finely suspended condition, and that gold assists by forming an amalgam in collecting together the metallic particles thus obtained in suspension. The method, briefly, is to add stannous chloride to the very dilute mercurial solution and then to pour the resulting mixture on an asbestos filter containing gold. Gold alone is not sufficient to completely extract the suspended mercury according to the authors' experiments. The asbestos is prepared by soaking it with gold chloride and carefully igniting the material, when a residue of finely divided gold remains. The filtrate is clear and the whole of the mercury is retained by the gold asbestos. The asbestos may be dried and weighed and then ignited, the loss equalling the mercury in the given quantity of fluid such as urine. The method is very ingenious, but to us it appears unnecessarily complicated for the simple end in view. We have found that by merely using the terminals of a battery the mercury in the urine may be completely separated in a short time even when present in very small quantities.

THE chief surgeon to the American forces in the Philippines has cabled to the Surgeon-General at Washington that three cases of bubonic plague have occurred among the natives.

MEDICAL FEES UNDER THE POOR-LAW.—At a meeting of the St. Germans (Cornwall) Board of Guardians held on Jan. 4th the chairman stated that Mr. Preston Thomas, who had acted as arbitrator between the board and Mr. Gill, district medical officer, had given his decision in favour of the guardians. As reported in THE LANCET of July 29th, 1899 (p. 278), Mr. Gill had attended one of his club patients for a compound fracture of the leg; the man eventually became a pauper patient of Mr. Gill, and as the case required much care he asked the guardians for extra fees. The board at first allowed Mr. Gill £5 but afterwards, saying they had doubts about the legality of the course, decided not to pay the sum. This naturally caused friction between the guardians and the medical officer and it was eventually decided to appoint an arbitrator.

THE WAR IN SOUTH AFRICA.

IT is not merely that the war is uppermost in men's minds, but it seems to fill them, for little else is talked about. Even the busy practitioner's thoughts must oscillate between the war and the influenza epidemic. If the South African Republics had been arming and preparing for years (even anterior to the Jameson raid) for this rebellion, how has it happened, it is asked, that the fact was unknown, or if known, why was it ignored, seeing that it could have but two meanings—namely, a menace to or war with this country? The Government would probably reply that if any step had been taken at that time to demand an explanation from the Boer Government the Opposition would immediately have treated their action as only calculated to force the Boers into war, and the nation would in all probability have backed them in that view. It must be admitted that there is some force in that argument, seeing that a policy of patience and forbearance was once the dominant cry, whereas it is now quite the reverse. But if the Government was convinced that the facts were as they were and that they could only lead to one logical conclusion, how was it that they had not the courage of their opinions? A strong and decided course of action if adopted long ago would probably have averted war altogether, and it certainly would have put us into the best and most favourable position for successfully undertaking it. Further, war having become inevitable after the Boer ultimatum, why was not a large and continuous supply of troops and guns sent out and accumulated in South Africa with the view of carrying out a well-defined strategical object by means of a concentrated force, instead of allowing our strategical plans to be frustrated as they have been, owing to the necessity of dividing and crippling our army in its efforts to relieve so many besieged garrisons? There cannot be much doubt that all our present difficulties in this South African campaign have arisen in this way. The generals and troops have found themselves face to face with the most difficult and complicated situations. They have done their best under the circumstances; the troops have fought with a spirit, pluck, and valour that have never been surpassed, and under very trying conditions. It is, however, as easy to be wise after the event as it is useless to expect explanations at this time.

We are writing with the news from Ladysmith fresh in our minds. No one can read of the splendid and successful efforts of that garrison in its defence without a flush of pride and without cherishing the hope and belief that it will continue to hold out until it is relieved. Ladysmith is not by any means a Plevna. It is in reality and by natural position relatively a weak place for defensive purposes, but this renders its defence all the more praiseworthy and gratifying. "The enemy," Sir George White summarily states, "were repulsed everywhere with very heavy loss." Experience, however, warns us not to assume that the Boers will accept this as final. The immediate future of the war, at any rate, depends upon the result of Sir Redvers Buller's battle which many believe imminent. The position held by the Boers is one of great strength and it will require all the strategical and tactical skill of Sir Redvers Buller and his generals and a supreme effort on the part of the troops to carry it and relieve Ladysmith. We do not know whether the requisite transport is present or if all the arrangements have yet been completed, which, it goes without saying, must be complete before the attempt can be made with a reasonable and well-grounded assurance of success. Should it prove successful it will probably prove the beginning of the end, for the neck of the military power of the Boers will be broken.

We do not think that the extraordinary conditions of the warfare in South Africa have ever been realised in the way they should have been. Wherever the British forces have encountered the Boers in the open field they have beaten them and they have, again and again, even driven them out of strong positions. But for the first time in warfare, so far as we know, our troops have had to attack an invisible enemy armed with the best and most destructive weapons that modern science can devise. As an officer with Lord Methuen's force has graphically described it: "Perhaps you think it is easy to see a Boer, but it isn't. We have fought four tolerably big battles against them, but few of us have seen a single Boer. He is the invisible enemy. He lies in the grass, deep down in a trench, or behind a rock

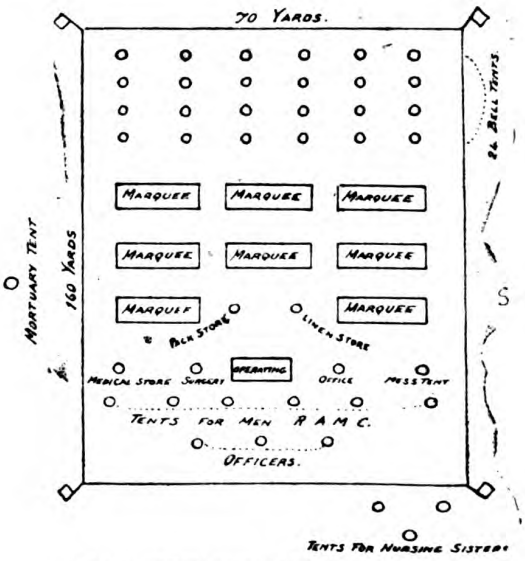
and spits death at us all day long, but we never see who is killing our men. An English soldier of imaginative mind might come to think of the enemy as a sort of nineteenth-century invention—a vapour like the colourless smoke of the new powder—or a demon or an essence." The Boers' tactics and method of fighting are traditional with them and they are always mounted, but these facts, curiously enough, seem to have been lost sight of, for the force sent against them were at first weak in mounted infantry, cavalry, and artillery. What with the sickness and the number of wounded in Ladysmith, the decreasing food supplies, the pressure of military duties, and the nervous tension which the strongest and bravest soldiers must experience under the conditions of life in that garrison, it speaks well for the discipline and fortitude of the troops that they have so far been able to repel all attempts at storming the place.

The general health of the army keeps very good. There is, however, as might be expected, a considerable amount of sickness incidental to hard field service anywhere—the more important diseases being enteric fever and dysentery. The climate is good, and we learn on all sides that wounds do well in South Africa. Transports keep arriving at the Cape and large additions are being made to the strength of the British force. The various Red Cross societies are working successfully in unison with the regular army medical services and are able to render very effective supplementary aid in different directions to that afforded by the regular supply branches of the army. The difficulty on war service not usually owing to any lack of material or equipment—for there is an abundance of stores of all kinds—but arises from the question of their distribution, so as to have them present at the place and moment they are wanted and of the particular kind required.

As our readers are aware, the nation shows no sign of wavering in its determination to carry on the war to a successful issue and the spirit and enthusiasm evinced in this country, in the colonies, and in India are remarkable and impressive. Not only are troops being sent from our colonies but field hospitals are being fully equipped in *personnel* and material, the display of generous patriotism being unanimous.

We would call particular attention to the very interesting and instructive notes kindly forwarded to us by Sir William Mac Cormac from the seat of war. The account given by him of the results of serious bullet wounds will come as an astonishing revelation to many surgeons.

(NOTES FROM SIR WILLIAM MAC CORMAC.)



(*Continued from page 59*)

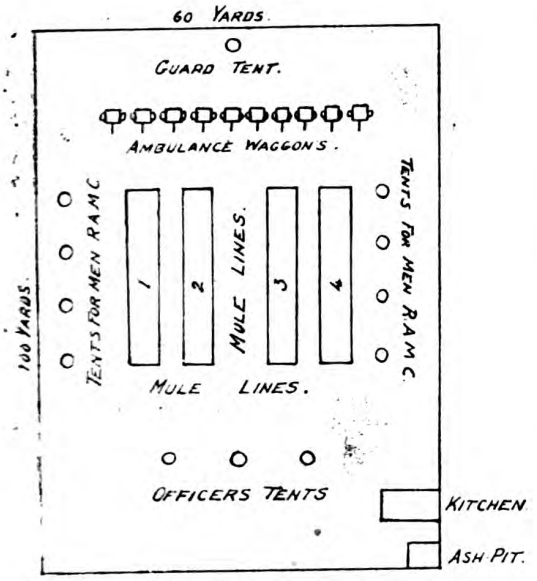
THE Fort Hospital at Pietermaritzburg is in charge of Lieutenant-Colonel Johnstone, R.A M C. There are under his command a varying number of officers of the Royal Army Medical Corps and five civil surgeons, also a staff of army nursing sisters, assisted by civil nurses and volunteers. This hospital originally consisted of 90 beds, but the number has now been increased to 550 by converting some barrack-rooms in the vicinity into hospital wards. More barrack-rooms are daily being suitably equipped, so that the number of beds available for sick and wounded (including 50 beds at the College Hospital, 70 at the Assembly House, and 50 at Grey's Hospital) is being increased until the total number of 1020 is reached. The situation is a commanding and healthy one on the top of a hill just outside the town, a site partly occupied in old days by a fort. There was no operating-room in the original hospital, so a suitable ward has been converted into one. The messhouse of the officers of the 5th Lancers has been converted into an officers' hospital, the anteroom and large messroom making two beautifully ventilated and comfortable wards.

The many paths in the hospital compound are still obstructed by barriers of barbed wire and barricades. These were constructed about a fortnight ago on the occasion of a threatened attack by the Boers on Pietermaritzburg. This scare impeded to a great extent the equipment of the hospital, as the whole of the *personnel* had to be transferred at very short notice to the College Hospital, the fort being completely deserted as a hospital and occupied by troops. On the retirement of the Boers beyond Estcourt a return journey of the hospital stores had to be made and much changing was needful, but the equipping has gone on rapidly since. There is, besides, within easy reach at Durban the hospital ship *Spartan* with 130 beds, and a register is kept of the transports to which the sick and wounded may be sent as well, and of the available medical staff and nurses. The ambulance is capable of taking 92 sick and wounded—82 lying down and 10 convalescents. Colonel T. J. Gallwey, the Principal Medical Officer, thinks this considerable provision is not altogether adequate to the possible requirements should a great battle be fought shortly on the Tugela river.

No. 4 Stationary Field Hospital arrived at Frere on the evening of Dec. 11th. It was detrained immediately and a site was chosen in the immediate vicinity of the railway line as being a convenient place for entraining the wounded. This hospital is to be the first stationary hospital on the lines of communication and will be the refuge of the sick disgorged by the four field hospitals with the four brigades as the latter move on in the fighting line. The next stationary hospital will be at Estcourt. Several of the bell tents were equipped ready for the reception of sick on the evening of arrival. By noon on the following day most of the tents were equipped and ready and had already received about 40 sick from the brigade field hospitals. This hospital consists of a fully equipped field hospital with the addition of eight large marquees, as is shown in the plan (see Fig. 1.) Its

FIG. 1.

Plan of No. 4 Stationary Field Hospital at Frere.



arrangement has been designed by Major R. Kirkpatrick, R.A.M.C., who is in command. The other officers are Major Mallins, Captain F. A. Symons, Lieutenant Simson, of the R.A.M.C., and Lieutenant-Quartermaster Short. There are 38 non-commissioned officers and men of the Royal Army Medical Corps, including compounders, cooks, &c., and also two army nursing sisters. At 4 P.M. on the evening of Dec. 11th this hospital (packed in trucks on a special train) was making its way into the railway station at Frere, and at the same hour on the 12th, a hospital ready for 150 sick (or more) distinguished by the Geneva Cross flag, occupied the ground. When the expected action on the Tugela river takes place there will be a body of 1200 civilian stretcher-bearers, under the command of regimental officers, whose duty will be that of conveying the wounded half way from the fighting line to the hospital, the first half of the journey being performed by other bearers of the same variety attached to the bearer companies. Each stretcher will be supplied with a squad of 25 bearers, this large number being told off so as to provide for frequent relief during a journey of possibly 30 miles. This arrangement has been devised by Colonel T. J. Gallwey, R.A.M.C., who has experienced the usefulness of this plan in Egyptian warfare. The country surrounding the Tugela river is so rough that the carriage of seriously wounded men by mule ambulance waggons would be extremely distressing to the patients. Each bell tent is supplied with four stretchers, each patient having a stretcher, mackintosh sheet, knife, fork, spoon,

basin, &c. The marquees are equipped with eight stretchers each and are reserved for the more serious cases.

We (myself and my secretary, Captain F. A. Symons, R.A.M.C.) put up our tents in the rear of the stationary hospital, arranging for our own cooking, &c. We have also been provided with mules and carts for our own use which are following us from Pietermaritzburg in charge of a sub-conductor of the Army Service Corps. We therefore form a separate little unit of our own, free to move as we like, taking up our headquarters at No. 4 Hospital. The water here is very scarce and muddy and requires careful boiling or filtering before use. Baths at present are practically disallowed.

Dec. 12th.—Our mules and carts arrived this morning, but are not yet ready for use as the wheels of the carts have become injured. Through the kindness of Major Ricketts, R.A.M.C., commanding No. 2 Bearer Company, we obtained the use of an ambulance waggon for to-day. This waggon is drawn by 10 mules. It is a 10-feet canvas-covered, heavily built waggon, fitted with two front seats and two side seats running the length of the waggon. These seats are well cushioned and the side ones may be turned up when not in use, so that two stretchers can be placed on the floor of the waggon. The outside is painted with a large red Geneva cross and the waggon also carries a Red Cross flag on a staff. Our waggon was driven by two Kaffirs, one handling the reins and the other wielding a huge whip like an 18-ft. salmon rod. We were also accompanied by two sergeants of the Royal Army Medical Corps. We first visited No. 2 Brigade and inspected the encampment of the field hospital and bearer company attached thereto (see Fig. 2).

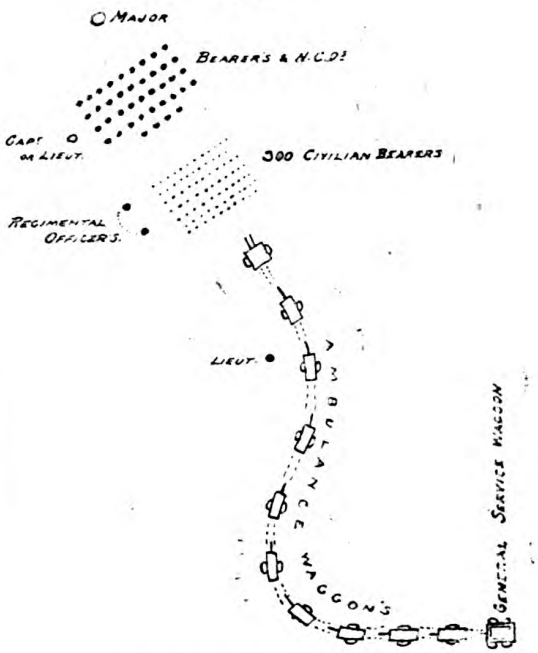


FIG. 2.

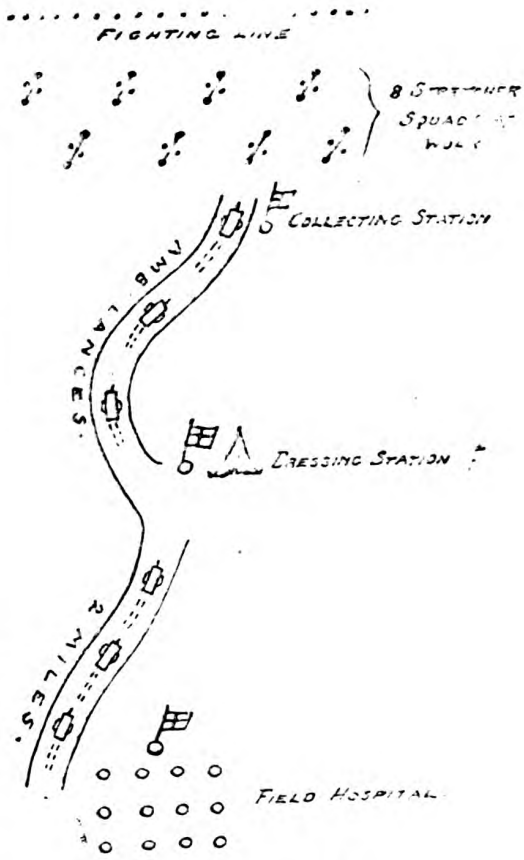
Plan of a Bearer Company Encampment.



These always work together and move with their brigade in action. The bearer company pick up the wounded, dress their wounds as well as possible, and send them on to their own field hospital. No. 2 Bearer Company is under the command of Major Ricketts, R.A.M.C., the two other officers being Lieutenant Palmer, R.A.M.C., and Lieutenant Wroughton, R A.M.C. This company is of the usual service strength and equipment, and its description applies to the other companies with this division. The officers and sergeant-major are all mounted. There are 32 bearers, making eight stretcher squads, and these, with the remainder of the company, performing the different duties described in the list below, march in front. These are followed by the water cart and then come 10 ambulance wagons. These bearer companies march into action (each with its own brigade), form their own collecting and dressing stations, pick up the wounded, apply first-aid dressings, pass the wounded to the rear through the collecting and dressing stations they have formed, and thus complete the transit of the wounded from the front line to the field

FIG. 3.

Plan of a Bearer Company on the March.

FIG. 4.

Plan of a Bearer Company in Action.

hospitals. The following plans will serve to explain their movements (see Figs. 3 and 4). The 300 civilian bearers mentioned above are shown as accompanying the company.

Strength and Distribution of a Bearer Company.

Major	1	Corporals	6
Lieutenants	2	Privates	8
Sergeant-Major	1	,, as cooks	3
Quartermaster-Sergeant	1	,, as bearers	32
Compounder	1	,, as servants	3
Sergeants	4	,, as supernumary	1
Bugler	1	Total	64

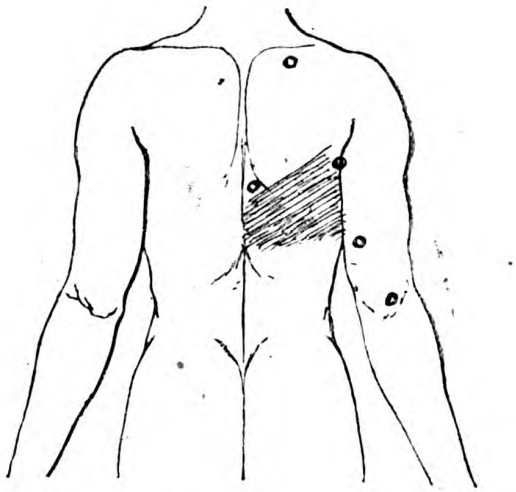
300 civilian bearers.

The field hospital of the 2nd Brigade is under the command of Major J. C. Culling, R.A.M.C., the junior officers being Captain H. J. Parry, Captain J. W. Jennings, Lieutenant J. W. Leake, and Lieutenant and Quartermaster H Spackman, R.A.M.C. It consists of the ordinary field hospital of 100 beds, about 40 of which are at present filled with cases of local complaints. These patients are being sent to No. 4 Stationary Hospital as soon as possible so as to allow the field hospital to move off with its brigade. After inspecting the hospital, which has been already carrying on its duties here for a fortnight, we again set forth in our waggon and drove to the 4th Brigade. Here we found the field hospital and bearer company encamped and arranged in exactly the same manner as those of No. 2. The field hospital is under the command of Major G. T. Goggin, assisted by Major F. S. Heuston, R.A.M.C., and two lieutenants. The bearer company is commanded by Major E. O. Milward, R.A.M.C. We found them all ready for a sudden departure and fully equipped and prepared for all emergencies of the field.

We then drove away in the direction of a hill about three miles distant from which we were told we could see the Tugela river and the Boer tents on the far side. The ground is very undulating and extremely bumpy for an ambulance waggon, which latter fact proved to us the efficacy of the 2400 bearers engaged by Colonel Gallwey.

On a hillock we espied as we went along what appeared to be a deserted encampment. This proved to be the place where a small party of Boers were suddenly disturbed at their meal about a fortnight ago by our troops. They evidently departed in a great hurry, for our sergeants ran up the hill to the spot and returned with two excellent chairs, ten good dinner-plates, a soup-tureen, vegetable-dish, and two stirrup-irons. The soup-tureen especially is now being made most useful for our little mess in camp, which Captain Symons and I run together. We reached our hill in time and were rewarded by seeing a most beautiful valley with the Tugela river running through it. About 15 miles away are the large range of hills in a dip of which lies Ladysmith. Chieveley railway station is indicated by a zinc-roofed house and a clump of trees. Some Boers' tents could be seen with glasses on the hills between us and Ladysmith and the camp of the Fusilier Brigade was situated about a couple of miles from Chieveley. The Naval Brigade have some guns at Chieveley and the Boers have some also on the hills across the river, the noise of which can easily be heard at Frere Camp.

If the expected battle comes off at Colenso, on the river, we shall easily be able to see the whole panorama from this little hill.



On our way back to camp we viewed the upturned armoured train and the grave of the poor fellows of the Dublin Fusiliers killed at the time of that disaster. The iron protection plates are pierced with many shell holes and the trucks themselves have rolled down the bank and are upside down. Numerous soldiers were employed in breaking off small fragments of iron work to take away as mementoes. Within 20 yards of the train is situated the grave of those killed. It has been very neatly covered over with cement by the Border Regiment, in which by means of inserting cartridge cases they have inscribed the following:—"Here lieth the remains of the men of the Dublin Fusiliers killed in the armoured train on Nov. 15th, 1899. R.I.P." The grave is neatly railed off by wire fencing and a wreath is on the top with a paper attached, on which is written—"A mark of respect from the Connaught Rangers." A party of soldiers stood round the spot sadly reading the inscription, the whole situation making a most pathetic scene and bringing home most vividly the sadness of war and the probable death still to come. We also inspected the remains of the iron railway bridge at Frere, the back of which is completely broken.

Dec. 13th.—The naval and Boer guns boomed away in the distance from daylight until about 9 A.M. We went again to our hill, but all was then quiet, and the Boers are reported to be retiring. Three out of the four brigades moved on to-day at 1 P.M., their destination being Chieveley, and unless the Boers are really retreating from Colenso, we expect to see the battle early to-morrow morning. The field hospitals have moved on with the brigades, and we saw one of them, fully packed, move off with all its baggage and tents, to be probably re-erected this evening at Chieveley. All the medical arrangements are fully complete in readiness for a big battle at any hour. The mail goes to-night and this report with it.

There are many interesting cases here at present. One cannot help contrasting with amazement the comparative harmlessness of the injuries so frequently inflicted with the Mauser rifle bullet with the frightful extent of the damage done by those of the needle-gun and the Chassepôt. To anyone familiar with the wounds caused by these weapons many of those inflicted by the Mauser rifle might be regarded as being somewhat of the character of a "pin-prick." Quite a large proportion of the wounded, in fact, have returned to duty, and several patients whom I have seen have been wounded for the second time at another engagement.

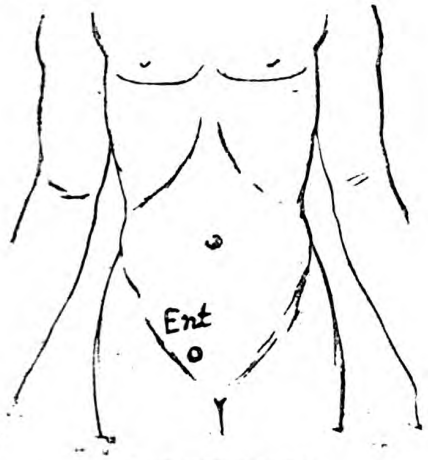
Private ——, aged 22 years, was wounded by a Mauser bullet at Beacon Hill, Estcourt. He states that the bullet came from a distance of 2000 yards. It entered his back at about one and a half inches above the middle of the spine of the left scapula. A short time after being wounded he suffered from slight hæmoptysis. A tender area of about two and a half inches in diameter, showing marked emphysema, made its appearance around the right nipple. His chest was skiagraphed and the conclusion thereby arrived at by Dr. Irvine (the civil surgeon in charge of the case) was that the bullet, having entered the left lung at the point above described, travelled across the thorax until it met the fourth right rib; it then changed its course upwards behind the third rib and was found embedded in the second interspace

FIG. 5.

The five external wounds are indicated. The shaded area indicates effusion.

parallel with the ribs, the base of the bullet being nearer the skin than the point. An incision was made by Dr. Irvine along the upper border of the third rib about two and a half inches external to the nipple line, cutting through the pectoral muscle and external intercostal muscle. The bullet was then extracted without any difficulty from between the two layers of intercostal muscles. The hæmoptysis ceased after the operation, and the patient now presents no symptoms whatever. The wounds are healed.

Private —— of the 2nd West York Regiment, aged 26 years, was wounded by Mauser bullets at Willow Grange on Nov. 23rd, receiving the following wounds: first, two perforating gunshot wounds of the right arm, entering at the outer side of the arm at one and a half inches above the



external condyle. The bullet ran up through the triceps, the exit being at the junction of the upper three quarters and lower quarter of the arm, about one inch posterior to the sulcus behind the outer border of the biceps on the inner side. It then entered the axilla a little posterior to the apex, and this wound can be probed for an inch. No bullet is discoverable either by probe or by x ray. He received, secondly, two wounds on the back—one just internal to the superior posterior angle of the right scapula, and another slightly to the right of the sixth dorsal vertebral spine. Possibly these four wounds, being more or less in line, were made by one bullet and the one opposite the sixth dorsal by another, and that this accounts for the chest symptoms. On admission to the hospital there were acute pain in the epigastrium and the lower costal region on the right side and increased vocal fremitus over the right lower costal region, and it was found on examining the patient on Dec. 1st that there was an area of effusion at the right base posterior to the angle of the scapula (see Fig. 5). There was paralysis, but no anæsthesia of the right lower extremity. This anæsthesia is improving, as is also the costal pain. The patient states that he first received the arm wound and subsequently that in the back. Civil Surgeon Irvine, who is in charge of the case, conjectures that the bullet entering at the sixth vertebra may have injured the pleura and lung, and that all the other wounds were caused by the first bullet. No bullet has as yet been discovered in the lung by means of the x rays.

Private —— of the 1st Manchester Regiment, aged 27 years, was hit at Elandslaagte by a Mauser bullet, the entrance wound being at the right side of the neck at the posterior border of the sterno-mastoid an inch above the clavicle, and the exit wound being at an exactly similar position on the left side of the neck. On admission the patient could not swallow properly or speak on account of pain in the larynx, but these symptoms rapidly improved, until at present, beyond a slight difficulty in swallowing, he is perfectly well.

Private ——, of the 2nd Gordon Highlanders, aged 26 years, was wounded by a Mauser bullet at Elandslaagte. The bullet entered the external surface of the left thigh at the junction of the upper and middle thirds. It passed transversely through the extensor muscles in front of the femur, emerging about an inch lower down than the entrance wound. It then entered the right thigh on the same level, passed behind the bone, and emerged on the outer side at the same level. There was hardly any hæmorrhage, and the patient completed the charge (of about 800 yards) after receiving these four wounds.

Private —— of the 2nd Gordon Highlanders, aged 22 years, was wounded by a Mauser bullet at Elandslaagte.

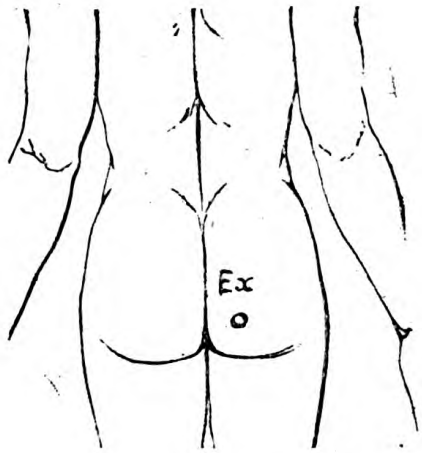


FIG. 6.

Shows entrance wound.

The entrance wound is an inch above the symphysis pubis and one inch external and to the right (see Figs. 6 and 7). The exit wound is one inch above the level of the anus and about two and a half inches external to the middle line in the right buttock. After being wounded he ran for about one-third of a mile without inconvenience. There was hardly any hæmorrhage, but the right testicle swelled up within an hour. He suffered for about a fortnight with pain at the root of the penis and on defecation, but there was no blood in the stools and he has now perfectly recovered.

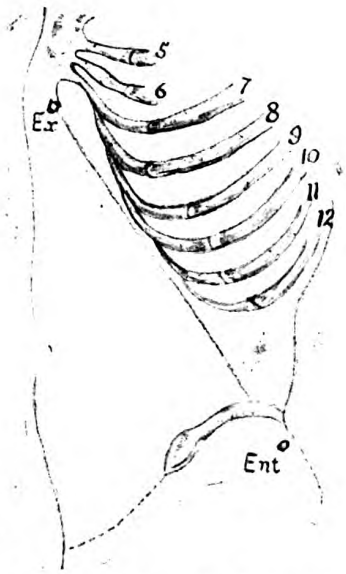

FIG. 7.

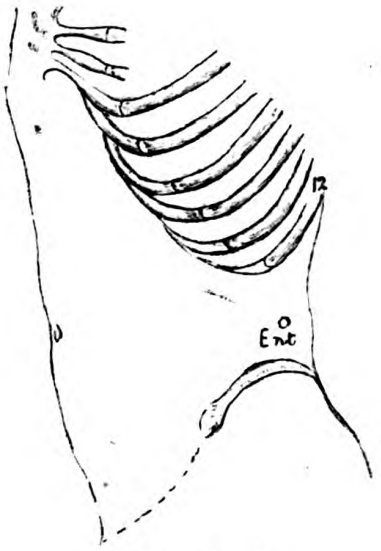
Shows exit wound.

Private —— of the 2nd West Yorks Regiment, aged 20 years, was wounded by a Mauser bullet from a distance of about 1500 yards (?) at the battle of Willow Grange on Nov. 23rd. There is a perforating wound of the abdomen. The bullet entered half an inch external to the posterior superior spine of the left ilium and pierced the ilium (see Fig. 8). The wound of exit is situated one and an eighth

FIG. .



Shows both entrance and exit wounds. The dotted ack suggests that the stomach was traversed.

inches below the level of the ensiform cartilage and one and three-eighths inches to the left of the middle line. It would seem that the bullet must undoubtedly have passed through the stomach. The wounds healed by first intention and the patient has suffered no inconvenience in any way, having eaten his food ever since the wound was received. He is now convalescent.

Private ——, of the 2nd West York Regiment, was

wounded by a Mauser bullet from a distance of 600 yards (?) on Nov. 23rd at Willow Grange (see Figs. 9 and 10). The bullet entered at two and a half inches above the crest of the left ilium, four inches from the spinal column. The exit wound is situated one and a half

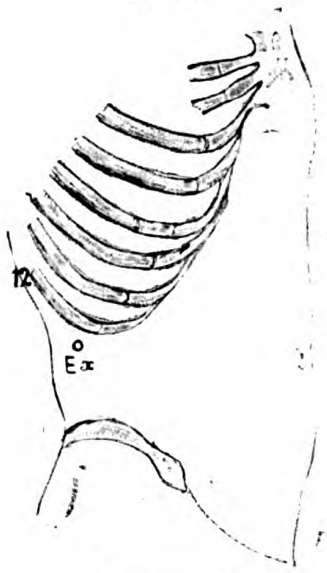


FIG. 9.

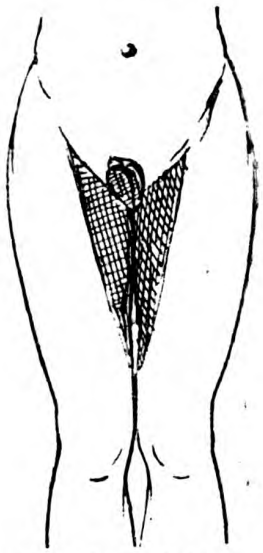
Shows entrance wound.

inches posterior to the anterior extremity of the twelfth rib on the right side. The wounds healed by first intention. The bowels have not been moved since the receipt of the wound and enemas have had no effect as the patient cannot retain them. Sulphate of magnesia and calomel have also been tried without effect. The

FIG. 10.



Shows exit wound.

patient states that he fell down immediately he was shot as his legs gave way, and on attempting to rise he found that his legs were disabled. On admission to the hospital it was found that both legs were partially paralysed but that sensation was not affected. The patient could control his bladder, but could not feel his urine passing away through the urethra on micturition. The paralysis in the lower extremities has been slowly disappearing, but it still exists to some extent in the left leg. There is, however, at present, a well-marked hyperæsthetic area on the inside of both thighs and in the perineal region (see Fig. 11). The colon and rectum still remain paralysed, no improvement having yet taken place, but sensation has returned in the urethra. From the relationship of the wound of entrance to the colon (and the present percussion resonance) there seems no doubt that the colon has been perforated.

A private of the Dublin Fusiliers was wounded at Talana on Oct. 20th. The bullet entered an inch above the root of the nose. The exit was at the junction of the frontal and

FIG. 11.

The shaded area indicates hyperæsthesia of inner surface of thighs and under surface of scrotum.

squamous portion of the temporal bone on the right side, about one and a half inches above the outer margin of the orbit. The bones were drilled without any fracturing, the entrance and exit wounds being exactly the same size. The brain substance protruded. The wounds were dressed with dry boric dressing on the field. The patient suffered no inconvenience whatever and the wounds were completely healed by the fourth day. Civil Surgeon Mate who records the case, states that he last saw the patient on Nov. 4th walking about the ward apparently perfectly well.

An officer was wounded at Talana on Oct. 20th. The bullet passed through the left antrum of Highmore, making its exit through the mastoid process on the same side. On Nov. 3rd the entrance wound had healed, but small spicules of bone had been removed from the exit wound. The patient was doing very well and suffered very little inconvenience except that of deafness on the left side.

Private ——, of the 1st Devon Regiment, was wounded on Oct. 21st at Elandslaagte at a distance of 400 yards. The entrance wound was in the left knee one inch below and one and a quarter inches behind the tibial insertion of the semi-membranosus. The bullet passed through the tibia and the knee-joint and made its exit through the external condyle of the femur, one and a quarter inches above the articular surface and in the middle of the antero-posterior diameter. Simple synovitis followed the wound, but the apertures healed by first intention. The synovitis is still slightly present.

A private was wounded at Estcourt on Nov. 23rd. The entrance wound was immediately below the ninth left costal cartilage and the exit wound was between the seventh and eighth ribs on the right side in the mid-axillary line. There was considerable shock and internal hæmorrhage was suspected. Laparotomy was performed by a civil surgeon from Johannesburg in the middle line above the umbilicus. When the abdominal cavity was opened it was found that the bullet had ploughed its way along the upper surface of

the liver, making a groove close to its anterior border, the length of which was about two and a half inches. There evidently had been very little hæmorrhage. The peritoneal cavity was washed out with saline solution and a strip of iodoform gauze was placed in the groove and brought out through the abdominal incision, thus forming a drain. This was removed on the following day. The abdominal incision was closed in three layers with silk and silkworm gut. A week after the operation, when the patient was last seen, he was progressing very favourably.

A private in the West Yorks Regiment was wounded at Willow Grange on a Thursday. The bullet entered the nape of his neck on the right side, opposite to the third cervical spine, one and a half inches from the median line, and emerged at the inner canthus of the left eye. Some loose pieces of bone, probably portions of the ethmoid, were picked out, but the man suffered no practical inconvenience. He sat up the same evening, on the next day he was reading the paper and smoking, and on the Saturday he was going about without any complaint of any kind.

In a man, who was lying down at the time, a bullet entered about the middle of the supra-spinous fossa of the left scapula, emerging to the left of the middle line at the margin of the scapula at the level of the fifth costal cartilage. On the second day the patient had some hæmoptysis which continued slightly on the two following days. The patient had no other complaints and was sent to Pietermaritzburg.

A trooper was shot on the railway line at a point just opposite to where the stationary hospital now is. The bullet entered a little above the junction of the middle and upper thirds of the right femur, on its outer side, about four inches below the tip of the great trochanter. The bullet, which was fired at a long range, passed through the femur, causing much comminution, and was felt under the skin on the inner side at about the same level but well behind the artery. The bullet was removed and the result was the same as in an ordinary simple fracture. There was shortening by three-quarters of an inch.

Private —— of the 1st Dublin Fusiliers whilst standing on the cow-catcher of the armoured train on Oct. 15th was struck by a fragment of shell on the right arm. On the patient being seen by Lieutenant Briscoe half an hour after the receipt of the injury it was found that the greater portion of the arm was torn away, leaving the humerus bare for several inches, especially on the inner side. The vessels and nerves were torn through completely, the arm being attached simply by strips of triceps and skin. The patient was suffering greatly from shock. The amputation was completed by dividing the remaining tissues so as to make a cover for the end of the bone, which was sawn square off. The brachial artery was tied and a drainage-tube was inserted, which was left in for three days. On removing this tube secondary hæmorrhage took place. The wound was laid open and the brachial artery was again tied in the wound, the ligature having slipped. The patient afterwards made a perfect recovery.

A colour-sergeant in the West Yorks Regiment had a peculiarly fortunate escape at Willow Grange. A bullet pierced his haversack and struck his dinner-knife at half an inch from the haft, breaking it clean across, the remaining portion being twisted half round. It then traversed a tin of ointment, broke the heavy clasp-knife hanging from his belt, gouged an inch and a quarter out of his dispatch-book (three-quarters of an inch thick) which was hanging beneath the knife, and entered his hip for about one-eighth of an inch, carrying a piece of shirt with it and making a very superficial wound.

(FROM OUR SPECIAL CORRESPONDENT AT THE BASE.)

The last engagement at Magersfontein swelled the list of wounded by 38 officers and over 460 men, the majority of whom reached here last week. The officers were accommodated in wards in the old station hospital, which has been incorporated into No. 1 General, and the men have been equally distributed between No. 1 and No. 2 General. I am glad to say that the wounds of the officers, with some few exceptions, have not been very serious and many are on the high road to recovery, the wounds being principally flesh ones of the extremities and in all these cases progress has been uninterrupted. Wounds of bones and joints, on the other hand, are more or less tedious and frequently require operation, the smashing power of the Lee-Metford being very apparent in contra-distinction to the clean perforated wounds caused by the Mauser. We have been obliged to open two more large wards for the accommodation of officers, besides taking a large portion of the Claremont Sanatorium for the less serious and convalescent cases. The latter institution is admirably adapted for the reception and treatment of the wounded, being situated in its own grounds and with every convenience for the comfort and welfare of patients. As there are at present no general hospitals in Natal we may expect a great number of wounded from the last battle at Colenso, which from all accounts seems to have been very disastrous as regards the number of casualties. We had a visit from Mr. Makins this morning; he was up at Modder River during the fight and had the opportunity of operating in several abdominal cases. He returns to-night up country in view of further engagements. The variety, and I may call it eccentricity, of the bullet wounds in this war—by this I mean the direction taken by the missiles and the marvellous escapes of big vessels and bones—would fill a good sized volume, but I have not, I am sorry to say, time to detail them and must leave it to those who have more leisure at their disposal. It requires a war like this to teach us how little damage (under favourable circumstances) a Mauser bullet through the lung seems to do. I have at present under treatment two such cases, one of which on admission had very slight hæmoptysis and spasmodic dyspnœa and the other simply presented no signs of lung injury whatever, though the course of the bullet was literally a penetrating one an inch above the right nipple in front, coming out slightly above the angle of the scapula behind. This patient, with the exception of slight shock when first wounded, has suffered absolutely no inconvenience and smokes his pipe with a philosophic calm which is interesting to watch. An amputation of the thigh in the lower third for traumatic aneurysm of the femoral is doing up to date quite well; another officer who, besides this injury, has a compound fracture of the right forearm and a nasty wound over the left orbit is making a bold bid for convalesence. Major R. W. E. H. Nicholson, R.A.M.C., has left us and Major R. W. Barnes has been put in charge of the officers' wards. These are the only changes in the *personnel* I have to chronicle, with the exception that our worthy Sergeant-Major Chalk has been promoted to the rank of lieutenant and quartermaster.

ASYLUM REPORTS.

The Retreat, York (Report for the year ending June 30th, 1899).—This institution has a unique and interesting history. In 1792 William Tuke, a member of the Society of Friends, became convinced that the methods of treatment of the insane, then prevalent, were unnecessarily harsh and severe. The foundation of an institution where the insane could be treated in a more humane and gentle way was decided upon, and in response to an appeal for support members of the Society of Friends contributed the funds necessary to provide "a retired habitation for 30 persons deranged in mind." In May, 1796, the present building (a central block with two wings) was opened. Subsequently, under the Lunacy Acts of 1845 and 1890, the Retreat has been registered as a "Hospital for the Insane." The government of the Retreat is vested in 40 directors, all of whom must be members of the Society of Friends. Four wings have been added since the building was opened—viz., a N.E. wing in 1812, a N.W. wing in 1827, a S.E. wing in 1852, and a S.W. wing in 1858. In 1881 an East Villa was built for gentlemen and in 1890 a West Villa for ladies. Voluntary boarders are received at the institution. The average number resident during the year of the report consisted of 166 patients—viz., 68 males and 98 females. The admissions during the year amounted to 37 and comprised 18 males and 19 females. The average weekly expenditure per patient, excluding the cost of new buildings, was £2 6*s.* 6*d.* The income from patients has been fully maintained and again exceeds that of any previous year. Owing to lack of space and consequent inability to admit many cases that applied for admission the admissions are slightly less than the average of recent years. Dr. Bedford Pierce, the medical superintendent, states in

his report that "rather more than one-half of the new patients admitted were deemed to be curable, but the remainder were decidedly unfavourable cases and had either been under care previously and failed to recover or were cases of long standing that had been treated privately. 13 of the new cases have had previous attacks and one lady has had no less than seven attacks before the present one. In 12 of the patients admitted there was evidence of an inherited tendency towards insanity." 11 patients recovered and were discharged, a ratio equal to 6 6 per cent. of the average number resident. There were 11 deaths to report during the year, a greater mortality than usual. The average age at death was 59 years, although two of the number were but 24 years of age. Two deaths were due to bronchitis and one each to pneumonia, phthisis, bronchopneumonia, general paralysis, and senile decay. One death (that of a female patient) was due to phosphorus poisoning. There was very little sickness among the patients or the staff apart from a few isolated cases of influenza. The principal event of the year has been the completion of the new buildings to provide a home for the nurses in June last. The cost of this has been estimated at about £2700, and donations towards the cost have amounted to £1887 up to the date of Sept. 11th last. Several structural improvements and additions to other parts of the building were arranged for at the same time and the total cost has been estimated to be slightly over £3900.

Glasgow District Asylum, Gartloch (Report for the year ending May 5th, 1899).—The average number of patients resident in the asylum during the year was 465 and comprised 236 males and 229 females. The total admissions during the year were 203—viz., 111 males and 92 females. Of these 140 were first admissions. Dr. L. R. Oswald, the medical superintendent, states in his report that seven of those admitted were over 70 years of age, two being over 85 years. "The nursing of these old people demands the greatest care and tact, for they are specially liable to accidents by reason of their frail condition and interfering ways. They must be kept apart from the acute and excited cases." Alcoholic intemperance is set down as having been the cause of the insanity in 50 of the persons admitted, but in many of these—as, indeed, in other cases—the illness was not due to one but to several causes, of which intemperance was the most prominent. "Intemperance, along with an enfeebled bodily condition, acting in conjunction with prolonged worry or mental strain, or following an influenzal attack, but with intemperance as the main factor," was the cause of insanity in the 50 cases referred to. General paralysis as a condition existed in 9 per cent. of the admissions, and in 16 per cent. a hereditary predisposition to insanity was established. The difficulty of obtaining reliable family histories was so great that it is considered probable that the proportion with hereditary taint was higher. During the year 98 patients were discharged as recovered, or 21 per cent. of the average population. Boarding-out, as a means of dealing with quiet and harmless cases, was largely practised during the year. 44 patients were thus sent out, but of that number seven were returned to the asylum for further observation. The deaths during the year numbered 38, or 8 per cent. of the average number resident. Of the deaths two were attributed to senile decay, three to cerebral hæmorrhage, seven to phthisis and tuberculosis, and 11 to general paralysis. There were 11 escapes during the year, seven of these being effected by patients on parole. The privilege of parole is extended to from 20 to 25 per cent. of the patients and it is much appreciated and seldom abused. Influenza visited the institution but it was not virulent; it lowered the health of many members of the staff, but was not in any case fatal. Work, especially out-of-door employment on farm and garden, for men and women has benefited many. The treatment of acute and curable cases by prolonged rest in bed has been practised with success. Recreation and treatment go hand-in-hand, the grounds adjoining the Loch affording a delightful summer resort for suitable cases. The Nurses' Home is now well on its way to completion and it is now ready for occupation.

Govan District Asylum, Paisley (Report for the year ending May 14th, 1899).—The average number resident during the year was 404, and comprised 203 males and 201 females. The admissions during the year were 342 in number, viz., 177 males and 165 females. 330 patients—171 males and 159 females—were first admissions. Of the 392 patients admitted 118 were transferred from other asylums. This high proportion of transfers is due to the increase of accommodation afforded by the new hospital block. This building, which practically completes the asylum, was formally opened on July 8th, 1898. 85 patients were discharged recovered, or 21 per cent. of the average number resident. 87 per cent. of all the recoveries took place within six months after admission. There were 12 re-admissions of patients who had been previously under treatment in the asylum. Mr. W. R. Watson, the medical superintendent, states in his report that there was no fatal or even very serious accident during the year. Satisfactory progress had been made in laying out the grounds and upwards of 120 male patients were regularly employed in this and other necessary outdoor occupations. The deaths numbered 44, or 11 per cent. of the average daily number resident. "This percentage is somewhat high, but when it is considered that 29 deaths were directly due to disease of the brain and spinal cord the numbers do not seem to call for any special comment here. ..... There were only two deaths from phthisis and these patients were suffering from advanced disease when received into the asylum." 14 deaths, the largest number due to any one illness, were attributed to general paralysis, four each were due to cerebral hæmorrhage and to cardiac disease, and two each to phthisis and to senile decay. The works for the disposal of the sewage by the bacterial method were formally opened on April 25th, 1899. The recently opened hospital section of the asylum for the special treatment of acute and curable cases has been liberally and suitably furnished and the arrangements of the building have been found to be well adapted to the purpose.

THE HEALTH OF RUSSIA, 1893-1895.[1]

THE most recently issued report of the Medical Department of the Russian Ministry of the Interior deals, not, as in previous issues, with the returns of a single year, but with those of three years. The three years in question are 1893, 1894, and 1895. During the first two the cholera epidemic, which had first reached Russia in 1892, was still active and in certain parts of the Empire very much more active than in the first year of its prevalence. Notwithstanding this fact the total recorded mortality in 1893 and 1894 was practically the same as (if anything, rather below) the average mortality of the three preceding years, though higher than that of 1886–88.

The population of the Russian Empire [2] in the years under review was estimated to be as follows:—

	1893.	1894.	1895.
European Russia	101,111,822 ...	102,664,841 ...	104,506,880
The Caucasus	8,177,452 ...	8,326,727 ...	8,599,593
Siberia	4,948,676 ...	5,006,773 ...	5,116,724
Central Asia	6,417,472 ...	6,554,495 ...	6,575,501
	120,655,422 ...	122,552,836 ...	124,798,698

It will be observed from these figures that the population has increased by over 4,000,000, or approximately 3½ per cent., in the course of two years. The increase is calculated by taking the difference between recorded births and recorded deaths in the period in question and adding the result to the number of the population at the beginning of the period. This natural increase in population was distributed over the three years in the following manner:—

	1893.	1894.	1895.
Recorded births	5,314,807 ...	5,479,213 ...	5,651,063
Recorded deaths	3,660,716 ...	3,774,488 ...	3,869,936
Natural increase...	1,654,091 ...	1,704,725 ...	1,781,127

It is pointed out in regard to the figures relating to the population of the empire that this method of estimating it in successive years has recently been shown to lead to results which are only approximately correct, and that almost certainly the figures here quoted are considerably above the truth. Thus, the population reckoned in this way gives for European Russia a population of 104, 506, 880

[1] Report of the Medical Department of the Ministry of the Interior, Part I. St. Petersburg, 1898.

[2] Excluding the Grand Dukedom of Finland.

at the opening of 1896, and (advancing to a later period than that covered by the report under notice) 106,200,000 at the beginning of 1897. But on Jan. 27th, 1897, a census of European Russia was taken by the method of actually counting heads, and in the result European Russia was found to contain only 103,631,340 inhabitants, or some 3 per cent. less than the estimated figure. This being so it is obvious that the birth-rates and death-rates calculated on the estimated figure are in reality below the truth.

In Central Asia and Siberia the population was reckoned at the time of the census in an indirect manner; the number of dwellings (houses, kibitkas, tents, &c.) was counted, and from four to six persons were supposed to dwell in each. The result was of necessity a mere approximation to the truth, and figures of birth-rates or mortality based upon it must be equally uncertain and may therefore be passed over without detailed notice.

In European Russia the birth-rate in the years in question was 46·1 in 1893, 46·4 in 1894, and 47·1 in 1895, or 46·6 for the average of the three years. The mortality, on the other hand, was 32·1, 32·2, and 32·5 in each of the three years, or 32·3 as an average for the whole period.

The following comparative table is published in the early pages of this report, showing the like statistics for the same period in the other countries of Europe:—

—	Birth-rate (per 1000).				Death-rate (per 1000).			
	1893.	1894.	1895.	Average, 1893-95.	1893.	1894.	1895.	Average, 1893-95.
European Russia...	46 1	46·4	47·1	46·6	32·1	32·2	32 5	32·3
Hungary	42·5	41·3	41 5	41·8	31·1	30·4	29·6	30·4
Austria	37·9	36·7	38·1	37·5	27·1	27·8	27·7	27·5
Italy...	36·8	35·8	35·1	35·8	25·4	25·2	25·2	25·2
Germany	36·7	35·9	36·1	36·2	24·6	22·3	22·1	23·0
France	23·1	22·3	21·9	22·4	22·6	21·3	22·3	22·2
Switzerland	28·4	28·0	28·0	28·1	20 4	20 6	19 7	20·2
Belgium	29·2	28·6	28·5	28·8	20 0	18·6	19·5	19·4
Holland	33 8	32·5	32·8	33·0	19·2	18·5	18 6	18·8
Scotland...	31·0	30·2	30 4	30·6	19·5	17·2	19·7	18·8
England	30·3	29·6	30·4	30·2	19·2	16·6	18·7	18·2
Ireland	23·0	22·9	23·2	23 0	17·9	18·2	18·4	18·2
Denmark	30·6	30·2	30·2	30·3	18·9	17·5	16·9	17·8
Norway	30·7	29·7	30·6	30·4	16·3	16·9	15·7	16·3
Sweden	27·3	27·0	27·5	27·3	16·8	16·3	15·2	16·1

A table of this kind presents many points of great interest. It will be observed that while Russia occupied the first position among the nations in regard to birth-rate with the remarkably high average of 46·6 births per 1000 inhabitants during the three years in question she at the same time had the highest death-rate. A general mortality of 32·3 per 1000 is a very high one and means that in many parts of the country that figure must be greatly exceeded. It is practically double the mortality which prevailed in Norway and Sweden at the same period and is 77 per cent. in excess of that recorded in our own islands. The excess of birth-rate over death-rate is, however, also remarkably high in Russia, and, accepting the figures as they stand, it would appear that that country is yearly adding by "natural increase" (or excess of births over deaths) from 14 to 15 persons to each 1000 of her population, while in England the natural increase is (or was in the years under review) only 12 per 1000 per annum, and in France it is reduced to a fraction of 1 per 1000, and in some recent years in the last-mentioned country there has been, not a natural increase, but a natural decrease of the population.

As was anticipated above, the death-rate in many parts of the country was much higher than that for the whole country. The highest death-rate recorded in any portion of European Russia in either of the three years was that in the Government of Samara in 1893, when the mortality was 50 per 1000. This high figure was doubtless caused by the epidemic of cholera in that year; but this Government has throughout returned an unusual number of deaths, the mortality there in 1894 being 38 5 and in 1895 44·0 per 1000 inhabitants. Siberia and Central Asia, statistics from which regions are, however, only approximate, returned comparatively low mortality figures, particularly the provinces of Semiretchinsk, Syr-Daria, and Turgai, where the death-rates varied between 17 6 and 20 per 1000.

The report explains the generally excessive mortality in the Russian Empire as being principally due to the extraordinary prevalence of zymotic or infectious disorders. With the exception of Hungary no other European nation suffers so widely from the principal zymotics. The explanation of this fact is not far to seek. Long experience in the west has shown that these diseases are to a very great extent controllable and some of them are almost preventable. But to control and prevent them requires many years' enforcement of strict sanitary legislation; it requires a permanent establishment of trained medical and sanitary officials and the introduction of extensive measures of sanitation—costly schemes of water-supply, of drainage, and the like—all of which imply an immense outlay of money extending over many years, and also a constant and detailed supervision by trained persons over the health conditions of every part of the country. For the present few of these essential factors in the fight with disease and death are possible in a country and population such as Russia and its inhabitants. Two and a half years ago we published, in a supplement to THE LANCET,[3] a very complete description of the sanitary service which has been organised in Russia, and it was pointed out there that the country is provided with a very admirable body of highly trained and able medical officers and sanitary officials and that a great deal had been done to cope with the most difficult problem of controlling the health of town and country. But it was also pointed out there—and the report now under review confirms the statement completely—that the natural difficulties to be overcome, the enormous area of the country, the scattered nature of the population, the character of the people (for the greater part an uneducated peasantry, living always in considerable poverty), and the climatic conditions—all tended to hinder the carrying out of public health measures and in many parts of the country have rendered it impossible to inaugurate even the simplest and least expensive of such measures.

A supplement[4] to the report under review has been published, subsequently to its issue, dealing with this question of the health of the towns in the Russian Empire in 1895. It is in the towns that most has been done of recent years to improve the state of the public health, but it is impossible to glance through the brief summaries of the conditions obtaining in the (about) 700 towns dealt with in this supplement and not be struck by the primitiveness of the sanitary arrangements described and by the general absence (with a few striking exceptions) of good water-supplies, good drainage systems, and of the other essentials to the proper health administration of a town. This being the case in the towns it is easy to conceive what the conditions must be in villages and in remote districts sparsely inhabited by oriental or half-savage nomad tribes.

The introduction to this supplement contains some interesting and instructive remarks on the progress of sanitary administration in Russia and elsewhere. It is pointed out that countries have usually passed through three periods in regard to their attitude towards preventive medicine. In the first period extraordinary measures to control diseases are only resorted to when some infectious disease has already become widely epidemic and is beginning to cause general alarm, or even horror, among the people. In the second period an advance is noted. Taught by experience in the past, early cases of any disease likely to become epidemic are noted by the authorities and measures are resorted to to try to extinguish the infection before it has given rise to a gigantic national or civic disaster. In the third period—the "sanitary period," to which most of the cultured nations have now advanced—a sanitary service is a permanent feature of the national or local organisation. Means for preventing the appearance of infectious disease and for doing away with those conditions which favour the prevalence of all disease, infectious or not, are constantly enforced, and it is recognised that the whole duty of governing authorities from a sanitary point of view is not confined to hurried and feverish measures aimed at the extinction of a few of the more strikingly fatal epidemic diseases.

[3] Medicine, Past and Present, in Russia. Supplement to THE LANCET August 7th, 1897.

[4] Report of the Medical Department of the Minister of the Interior "The Sanitary Condition of the Towns of the Russian Empire in the yea. 1895," St. Petersburg, 1899.

It is pointed out that the admirable effects of this system have up to the present been most clearly seen in England. "How fruitful the conduct of affairs on these principles," writes the author of the supplement, "may be is best seen in England, where, thanks to the constant regard for cleanliness of soil, water, and dwellings, such exotic diseases as cholera are not looked upon with dread, and where the mortality from typhoid fever, phthisis, and apparently from all other infective diseases, has been very greatly diminished." In Germany the effect of persistent and compulsory vaccination has almost exterminated small-pox. A measure of this sort in Russia would, it is pointed out, have saved over half a million lives in the seven years 1890–1897, to say nothing of the enormous amount of suffering from blindness and deformity which would have been avoided. The money loss to the country from this cause alone is enormous. Estimating the value of every Russian life at the low figure of 100 roubles (about £10 sterling; Farr estimated every English life at all ages at the value of £150; Rochard estimated every French life at 1037 francs, or rather over £40) small-pox has in those years cost Russia a sum of over 50,000,000 roubles. The loss from other infectious diseases is equally great.

Russia, it is admitted, is only on her way to the third or so-called "sanitary" period of her existence. Sanitary legislation is incomplete and is not the same in all parts of the country. With the introduction of local self-government in the form of *zemstvos* these bodies were granted powers of initiating compulsory public health measures, but there is no uniformity in the measures adopted. This, in the opinion of the author of this supplementary report, is one of the matters upon which reform is most needed. The description which follows, one by one, of the principal towns in the country is intended to form a basis for a new measure introducing a uniform sanitary law to be applicable to the whole country.

To return to the prevalence of zymotic diseases throughout Russia the following table is published indicating the extent to which that country is ravaged by these diseases in comparison with other European countries.

Deaths per 100,000 of the Population from Some of the Principal Zymotic Diseases.

	Small-pox.	Scarlet fever.	Diphtheria and croup.	Measles.	Whooping-cough.	Enteric fever.

* It is pointed out that in Russia, Scotland, England, and Ireland enteric fever is included among fevers of undetermined nature.

Figures relating to the sickness-rate from any disease are always, for obvious reasons, far from reliable, and they become still more so in a country where notification of disease is practised only to a small extent. This report contains certain figures of this kind and the most important of them are as follows. Of dysentery—apparently the most prevalent of all zymotic diseases in Russia—272,239 cases were reported, or 220 per 100,000 of the population. Of enteric fever 220,696 cases were recorded, of measles 194,972, of whooping-cough 197,643, and of diphtheria 190,117.

Out of a total registered number of cases of illness of 30,286,613 as many as 4,059,018, were due to infectious diseases (in which are included syphilis with 775,457 cases, other venereal diseases, phthisis, and pneumonia).

Before closing this brief notice of two instructive volumes it may be pointed out that while in the Russian Empire generally the births largely exceed the deaths, in a few places the reverse is the case. Excluding the exceptional year of cholera prevalence, 1892, a natural decrease of population has been observed in 20 towns. In eight towns, among which are Kazan, Samara, Saratof, and Simbirsk, an excess of deaths over births was observed in five out of the ten years 1887–1896. In the four towns, Astrakhan, Kazan, Saratof, and Simbirsk, the births in that decade numbered 158,687 and the deaths 164,875. A similar decrease has also been observed in some towns in the following governments: Voronezh, Kaluga, Moscow, Tula, St. Petersburg, Tambof, and Yaroslav.

PALERMO: ITS FUTURE AS A HEALTH RESORT.

"THE Golden Shell," as the great Sicilian seaport is picturesquely called, is at present acting as hostess to a number of British medical men, invited by her most prominent citizens to take note of her advantages as a winter resort for the invalid and as the seat of a new sanatorium for the treatment of tuberculosis on the lines proposed by Dr. Cervello, professor of pharmacology in the local university. Her claims to professional notice in both respects—as a winter city and as an advanced post in the "crusade against tuberculosis"—are familiar to our readers. Some years ago a Commissioner specially deputed by THE LANCET contributed to our columns an elaborate account of the many advantages—climatic, meteorological, and topographical—enjoyed by Palermo, and from time to time, in articles entitled "Italy's Opportunity," THE LANCET has indicated how the falling-off, conspicuous these last few seasons, in the favour hitherto shown by the English-speaking world to the French Riviera might be profitably utilised, not only by the Riviera Levante but by the Riviera Napolitana and the Riviera Siciliana. Again, our Rome correspondent[1] was the first to draw attention to the treatment of tuberculosis devised by Professor Cervello—a treatment consisting primarily of medicated inhalations, followed up by special dietetics and by such general therapeutics as the genial Palermitan climate, with its combination of marine and mountain air, is peculiarly fitted to reinforce. So encouraging had this treatment proved in Professor Cervello's hands that several of the most philanthropic of the citizens of Palermo—we may instance the enlightened and liberal Commendatore Florio and his right-hand man in all public-spirited enterprise, the Baron Fassini—founded a sanatorium for its more extended practice. The two undertakings, indeed—the development of the lovely Sicilian seaport as a winter city and the attraction created for her as a centre of expert treatment in pulmonary disease—form the "leit-motif" of the hospitality now extended by the Commendatore Florio and his friends to British medical men.

On their way to Palermo Signor Florio's guests—among whom may be mentioned Sir T. Lauder Brunton, Sir Walter Foster, Professor Clifford Allbutt, and Dr. Patrick Manson—made a brief halt in Rome and, escorted by Dr. Luigi Sambon of the University of Naples, whose connexion with the South Kensington Museum and the London School of Tropical Medicine peculiarly fitted him for the task, visited the chief scientific institutes attached to the Roman University. Interested in the recent work on malaria by Professor Grassi and Professor Celli and Dr. Bignami and Dr. Dionisi, they spent some hours in Professor Celli's Istituto d'Igiene and Professor Grassi's laboratory and then and there initiated reciprocal relations between the Italian "Società per lo Studio della Malaria" and the London School of Tropical Medicine. Another visit of an equally gratifying kind was made to the "clinica chirurgica" of Professor Durante, of the Roman University, where a case of very grave cerebral tumour on which Durante had operated 16 days before by the method associated with his name was seen in full convalescence. Thereafter the guests, under the guidance of Professor Durante, went over the Policlinico, or such portions of the vast building as are now completed. This magnificent edifice, described in

[1] THE LANCET, May 13th and 20th, 1899, pp. 1333 and 1398.

THE LANCET of March 31st, 1894, the creation of Dr. Baccelli, evoked much admiration for its architectural convenience and its unique arrangements for combining clinical with experimental observation and research. A final visit to His Excellency the Minister of Public Instruction (Dr. Baccelli) elicited the most cordial expressions of sympathy between the two medical schools, Italian and British, concluding by Dr. Manson's inviting Dr. Baccelli to participate in person at the opening next May of the London School of Tropical Medicine. His Excellency cordially accepted the invitation, subject, of course, to his having the necessary time at command, and he will, it is understood, not only honour the occasion by his presence, but will enhance the interest of the proceedings by an address on the subject of Malaria, presumably in its clinical aspects. On the next day the visitors left Rome for Naples, whence they embarked for Palermo.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

DURING the week ending Dec. 30th, 1899, 5040 births and 6700 deaths were registered in 33 of the largest English towns. The annual rate of mortality in these towns, which had shown a continuous increase from 18 9 to 27·5 per 1000 in the four preceding weeks, further rose to 30·6 in the week under notice The rates in the several towns ranged from 17·6 in Huddersfield, 19 4 in Burnley, 20 2 in Cardiff, and 21 3 in Halifax, to 39 3 in Wolverhampton, 39 5 in Preston, 42·1 in Portsmouth, and 49 7 in Plymouth. In London the rate was 35·2 per 1000, while it averaged 26 9 in the 32 provincial towns. The 6700 deaths from all causes in the 33 towns included 524 which were referred to the principal zymotic diseases, against 501 and 578 in the two preceding weeks; of these, 164 resulted from measles, 122 from diphtheria, 102 from whooping-cough, 52 from "fever" (principally enteric), 37 from scarlet fever, 37 from diarrhœa, and 10 from small-pox. The lowest zymotic death-rates were recorded in Croydon, Bristol, Derby, and Birkenhead; and the highest rates in Blackburn, Preston, Sheffield, and Hull. Measles was proportionately most fatal in Salford, Preston, Bradford, Sheffield, Hull, and Newcastle; whooping-cough in Portsmouth, Norwich, Salford, Blackburn, and Newcastle; and "fever" in Plymouth. The mortality from scarlet fever and from diarrhœa was not excessive in any of the large towns. The 122 deaths referred to diphtheria included 56 in London, 18 in Sheffield, six in Leeds, five in West Ham, and five in Manchester. The 10 fatal cases of small-pox in the 33 towns were all registered in Hull, and seven small-pox patients were under treatment in the Metropolitan Asylums Hospitals on Saturday, Dec. 30th, 1899. The number of scarlet fever patients in these hospitals and in the London Fever Hospital was 2881, the numbers having decreased from 3578 to 2916 at the end of the six preceding weeks; 161 new cases were admitted during the week, against 277, 180, and 209 in the three preceding weeks. Influenza was stated to be the primary cause of 193 deaths in London during the week, showing an increase of 124 upon the number in the preceding week. The deaths referred to diseases of the respiratory organs in London, which had been 548, 646, and 968 in the three preceding weeks, amounted in the week under notice to 1172, and were 586 in excess of the corrected average. The causes of 108, or 1·6 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Leeds, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Halifax, and Sheffield.

In 33 of the largest English towns 7145 births and 6870 deaths were registered during the week ending Jan. 6th. The annual rate of mortality in these towns, which had increased from 18·9 to 30 6 per 1000 in the five preceding weeks, further rose last week to 30·9. In London the rate was 37·1 per 1000, while it averaged 26·8 in the 32 provincial towns. The lowest death-rates in these towns were 12·5 in Burnley, 17·2 in Cardiff, 17·6 in Gateshead, and 18·7 in Oldham; the highest rates were 40·5 in Croydon, 40 8 in Nottingham, 42·5 in Preston, and 44·9 in Brighton. The 6870 deaths in these towns included 506 which were referred to the principal zymotic diseases, against 578 and 524 in the two preceding weeks; of these 156 resulted from measles, 121 from diphtheria, 93 from whooping-cough, 55 from "fever" (principally enteric), 40 from scarlet fever, 34 from diarrhœa, and seven from small-pox. No fatal case of any of these diseases occurred last week either in Plymouth or in Gateshead; in the other towns they caused the lowest death-rates in Croydon, Brighton, and Sunderland, and the highest rates in Salford, Preston, Sheffield, and Hull. The greatest mortality from measles occurred in Cardiff, Leicester, Salford, Preston, Huddersfield, Halifax, and Hull; from scarlet fever in Burnley; and from whooping-cough in Portsmouth, Norwich, Liverpool, Bolton, and Salford; the mortality from "fever" and from diarrhœa showed no marked excess in any of the large towns. The 121 deaths from diphtheria included 58 in London, 17 in Sheffield, six in Liverpool, five in Leeds, four in West Ham, and four in Leicester. Seven fatal cases of small-pox were registered last week in Hull, but not one in any other of the 33 large towns. There were eight small-pox patients under treatment in the Metropolitan Asylums Hospitals on Saturday last, Jan. 6th, against five and seven in the two preceding weeks; one new case was admitted during the week, against five and two in the two preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2730, against numbers decreasing from 3578 to 2881 at the end of the seven preceding weeks; 186 new cases were admitted during the week, against 180, 209, and 161 in the three preceding weeks. Influenza was certified as the primary cause of 316 deaths in London. The deaths referred to diseases of the respiratory organs in London, which had increased from 324 to 1172 in the seven preceding weeks, further rose last week to 1221, and were 558 above the corrected average. The causes of 99, or 1·4 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Leicester, Bolton, Newcastle, and in seven other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns the annual rate of mortality, which had been 20 0, 21·5, and 22 6 per 1000 in the three preceding weeks, further rose to 27·2 during the week ending Dec. 30th, 1899, and was 3·4 per 1000 below the mean rate during the same period in the 33 large English towns. Among these Scotch towns the death-rates ranged from 20 2 in Leith and 22 6 in Aberdeen to 34·2 in Greenock and 41·2 in Paisley. Of the 829 deaths in these towns 31 were referred to measles, 17 to whooping-cough, 17 to diarrhœa, seven to scarlet fever, seven to diphtheria, and six to "fever"; in all, 85 deaths resulted from these principal zymotic diseases, against numbers increasing from 69 to 84 in the three preceding weeks. The zymotic death-rate in these towns averaged 2 8 per 1000, being 0 4 above the mean rate during the week from the same diseases in the 33 large English towns. The 31 fatal cases of measles showed a decrease of six from the number in the preceding weeks, and included 19 in Glasgow, and three each in Dundee, in Paisley, in Greenock, and in Perth. The deaths from whooping-cough, which had been 18 and 12 in the two preceding weeks, rose again in the week under notice to 17, of which 11 were registered in Glasgow. The fatal cases of diarrhœa, which had decreased from 20 to 14 in the three preceding weeks, rose again to 17 during the week, and included four in Glasgow, four in Dundee, and four in Greenock. Of the seven deaths from scarlet fever four were recorded in Glasgow, where four of the six fatal cases of "fever," were also registered. The deaths referred to diphtheria, which had been two and three in the two preceding weeks, further rose during the week to seven, and included three in Glasgow, and two in Edinburgh. A marked increase in the mortality from diseases of the respiratory organs occurred, 253 deaths from these diseases being registered, showing an excess of 70 over the number in the preceding week and more than twice the number in the corresponding period of last year. The causes of 49, or nearly 6 per cent., of the deaths in these eight towns in the week under notice were not certified.

The annual rate of mortality in the eight Scotch towns, which had increased from 20·0 to 27·2 per 1000 in the four-

preceding weeks, declined again to 25·6 during the week ending Jan. 6th, and was 5·3 per 1000 below the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14·6 in Leith and 18·5 in Perth to 30·0 in Greenock and 35·2 in Paisley. The 792 deaths in these towns included 27 which were referred to measles, 17 to diarrhœa, nine to whooping-cough, six to scarlet fever, three to diphtheria, and two to "fever." In all 64 deaths resulted from these principal zymotic diseases, against numbers increasing from 69 to 85 in the four preceding weeks. These 64 deaths were equal to an annual rate of 2·1 per 1000, which was 0·2 below the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had been 37 and 31 in the two preceding weeks, further declined to 27 last week, and included 20 in Glasgow, four in Paisley, and two in Greenock. The deaths from diarrhœa, which had been 14 and 17 in the two preceding weeks, were again 17 last week, of which eight were registered in Glasgow, four in Dundee, and two in Edinburgh. The fatal cases of whooping-cough, which had been 12 and 17 in the two preceding weeks, declined again to nine last week, and included six in Glasgow and two in Aberdeen. The deaths from scarlet fever, which had been eight and seven in the two preceding weeks, further declined last week to six, of which four occurred in Glasgow, where the two fatal cases of "fever" were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had increased from 128 to 253 in the six preceding weeks, declined again to 236 last week, but were 113 above the number in the corresponding period of last year. The causes of 33, or more than 4 per cent., of deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 38·2 and 42·5 per 1000 in the two preceding weeks, declined again to 41·8 during the week ending Dec. 30th, 1899. The death-rate in the city during the four weeks ending on that date had averaged 40·3 per 1000, against an average rate of 27·8 in London and 19·8 in Edinburgh. The 280 deaths registered in Dublin during the week under notice were 5 below the number in the preceding week; of these, 22 resulted from the principal zymotic diseases, the numbers having declined from 72 to 38 in the six preceding weeks. These 22 deaths included 15 which were referred to measles, two to whooping-cough, two to "fever," one to scarlet fever, one to diphtheria, and one to diarrhœa. The zymotic death-rate was equal to 3·3 per 1000, the death-rate from the same diseases being 2·1 in London and 0·9 in Edinburgh during the same period. The fatal cases of measles, which had been 23 and 24 in the two preceding weeks, declined again to 15 during the week. The deaths from whooping-cough, which had been three and two in the two preceding weeks, were again two. The two fatal cases of "fever" showed a slight decline from the number in the preceding week. The mortality from scarlet fever corresponded with that in each of the three preceding weeks, while the deaths from both diphtheria and diarrhœa were less than they had been in any recent week. Of the 280 deaths in Dublin during the week 45 were of infants under one year of age and 92 of persons aged upwards of 60 years, the deaths of infants and of elderly persons being respectively nine and 17 in excess of the numbers in the preceding week. Eight inquest cases and seven deaths from violence were registered, and 89, or nearly a third, of the deaths occurred in public institutions. The causes of 28, or 10 per cent., of the deaths the city in the week under notice were not certified.

The death-rate in Dublin, which had been 42·5 and 41·8 per 1000 in the two preceding weeks, rose again to 50·3 during the week ending Jan. 6th. During the thirteen weeks ending Saturday last the death-rate in the city averaged 38·2, the rate during the same period being 22·8 in London and 18·6 in Edinburgh. The 337 deaths registered in Dublin during the week under notice were 57 in excess of the number in the preceding week, and included 18 which were referred to the principal zymotic diseases, against 38 and 32 in the two preceding weeks; of these, 10 resulted from measles, five from "fever," two from diarrhœa, one from whooping-cough, and not one from either small-pox, scarlet fever, or diphtheria. These 18 deaths were equal to an annual rate of 2·7 per 1000, the zymotic death-rate during the same period being 2·1 in London and 0·3 in Edinburgh. The fatal cases of measles, which had been 24 and 15 in the two preceding weeks, further declined to 10 last week. The deaths referred to different forms of "fever," which had been two, three, and two in the three preceding weeks, rose again last week to five. The fatal cases of diarrhœa, which had been five and one in the two preceding weeks, rose again to two last week. The mortality from diphtheria showed a decline from that recorded in recent weeks. The 337 deaths in Dublin last week included 47 of infants under one year of age and 119 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons were in excess of those recorded in any recent week. Seven inquest cases and four deaths from violence were registered, and 102, or nearly a third, of the deaths occurred in public institutions. The causes of 19, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

EMENDATIONS IN THE ROYAL NAVY MEDICAL SERVICE.

WITH a view of obtaining the best surgical skill in our naval hospitals we understand that the Board of Admiralty have decided that a larger proportion of promotions to the rank of Deputy Inspector-General of Hospitals and Fleets shall be made by special selection with reference to this most important part of the duties of these officers.

We are also glad to learn that in future a Surgeon in the navy will attain to the rank of Fleet Surgeon after a period of 20 years in the service instead of after 20 years of full pay service as has previously been the rule.

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified: — Surgeons: H. Spicer to the *Duke of Wellington;* M. Cameron to the *Northampton*, for the *Curaçoa;* F. C. B. Gittings to the *Mars;* G. E. Macleod and R. J. Mackeown to the *Europa;* and George A. S. Bell, to be lent to assist the Board of Army and Medical Officers in the physical examination of candidates for commissions in the Royal Marines; Fleet Surgeon S. Keays to the *Ramillies*.

ROYAL ARMY MEDICAL CORPS.

Captain G. A. T. Bray, from the Seconded List, to be Captain, vice M. L. Hughes, killed in action. Major F. J. Morgan has embarked for South Africa. Lieutenant-Colonel W. W. Kenny is appointed to the charge of No. 5 Stationary Hospital for South Africa.

INDIA AND THE INDIAN MEDICAL SERVICES.

Major D. G. Crawford, Officiating Civil Surgeon of the 24-Parganas, is allowed furlough for one year and six months. Lieutenant-Colonel T. Grainger, Officiating Civil Surgeon of Darbhunga, is allowed furlough for two years. Captain H. M. Earle, Resident Medical Officer, Medical College Hospital, Calcutta, is appointed to act as Civil Surgeon of Shahabad during the absence on leave of Lieutenant-Colonel W. Flood Murray until further orders. Captain H. J. Walton is appointed to act as Resident Medical Officer, Medical College Hospital, Calcutta, during the absence on deputation of Captain H. M. Earle until further orders. The services of the undermentioned officers are replaced at the disposal of the Military Department:— Major A. E. S. Searle, 14th Bombay Infantry, and Captain E. G. R. Wilkins, 14th Bombay Infantry. The services of Lieutenant H. H. Sproule, 1st Bengal Lancers, are replaced at the disposal of the Military Department. The services of Captain A. P. Bateman-Champain, 2nd Battalion, 3rd Gurkha Rifles, are placed temporarily at the disposal of the Government of the North-Western Provinces and Oudh for employment on plague duty. The services of Major A. R. W. Sedgefield (Bengal) are placed temporarily at the disposal of the Government of the North-Western Provinces and Oudh. The services of Lieutenant F. P. C. Keily, 1st Bombay Infantry, are replaced at the disposal of the Military Department. Lieutenant-Colonel B. M. Blennerhassett, R.A.M.C., to officiate on the Administrative Medical Staff of the Army with the temporary rank of Colonel.

VOLUNTEER CORPS.

Artillery: 1st Ayrshire and Galloway: Surgeon-Captain D. Lawrie resigns his commission. 3rd Lancashire: Surgeon-Lieutenant-Colonel A. A. Corte resigns his commission, with permission to retain his rank and to wear the uniform of the corps on his retirement. *Rifle:* 1st Volunteer Battalion the Northumberland Fusiliers: Thomas Woodman to be Surgeon-Lieutenant. 1st Volunteer Battalion the Royal Warwickshire Regiment: Alexander Henry McDougall to be Surgeon-Lieutenant. 1st Volunteer Battalion the Lincolnshire Regiment: Thomas Walter Alfred Daman to be Surgeon-Lieutenant. 1st Volunteer Battalion the Essex Regiment: Arthur Butler Harris to be Surgeon-Lieutenant.

VOLUNTEER INFANTRY BRIGADE.

Forth: Surgeon-Lieutenant-Colonel C. W. MacGillivray, the Queen's Rifle Volunteer Brigade the Royal Scots, to be Brigade-Surgeon-Lieutenant-Colonel on appointment as Senior Medical Officer to the Brigade and to be seconded whilst holding the appointment.

TRANSVAAL WAR NOTES.

Mr. Langman, the treasurer of the Portland Field Hospital, has offered to equip a similar hospital entirely at his own expense. This offer, which may eventually cost Mr. Langman £15,000, has been accepted, and the donor's son (Lieutenant Langman) has been appointed treasurer and ordnance officer. Dr. Conan Doyle will act as medical secretary and registrar and Mr. Robert O'Callaghan as chief surgeon. Three other medical men will also be appointed on the staff of the hospital and on its arrival on the lines of communication a major of the Royal Army Medical Corps will be placed in charge for details, &c. It is expected that the hospital will be completed in time to start for South Africa early next month.

A hospital for the use of the Imperial Yeomanry in South Africa is in course of organisation by a committee of ladies in conjunction with the Princess of Wales. The total sum received in aid of this scheme now exceeds £13,500. Towards this amount the Prince of Wales gave £100 and the Duchess of York £25. Mr. A. D. Fripp has been appointed chief surgeon to the Imperial Yeomanry.

We learn that a "flying hospital"—i.e., a car fitted with operation case, splints, dressings, and a small supply of drinkable water—has been devised by Dr. Horace Manders. The car is drawn by two horses, can keep up with cavalry, and can go anywhere that horse artillery can go. It is intended that one of these cars should accompany the Imperial Yeomanry regiment which is just upon the point of starting. The cost will be raised by subscription.

As we announced last week, Sir William Thomson has been appointed one of the chief surgeons to Lord Iveagh's Irish Hospital. He will, we understand, be accompanied by Mr. George Stoker. Mr. A. R. Friel will take charge of the Roentgen ray apparatus. Captain W. T. Mould, R.A.M.C., is the officer selected by the War Office for attachment to the hospital for administrative purposes.

Surgeon-Major E. L. Freer (Army Medical Reserve) and Surgeon-Captain W. P. Whitcombe, both of the 1st Volunteer Battalion Royal Warwickshire Regiment, have placed their services at the disposal of the War Office and have been accepted for service in South Africa.

DEATHS IN THE SERVICES.

Inspector-General of Hospitals and Fleets Garland William Langdon Harrison, on Dec. 30th, at "Hilton," Newton Abbot, Devon, from pneumonia following an attack of influenza. The deceased, who was 62 years of age at the time of his death, was the son of the late Dr. G. F. B. Harrison of Devonport and took the qualifications of M.R.C.S. and L.S.A. in 1858 and 1869 respectively. He entered the Royal Navy as surgeon in the former year and retired with the rank of inspector-general of hospitals and fleets in December, 1893.

Deputy-Surgeon-General David Cullen, on Jan. 4th. He served with the Army Medical Department from 1854 to 1869, with the 4th Light Dragoons, the 3rd Battalion Rifle Brigade, and the 17th Lancers. He was present at the siege and fall of Sebastopol and with the cavalry expedition to Eupatoria (medal and clasp and Turkish medal). He also received the medal and clasp for services during the Indian Mutiny, having been present at the final capture of Lucknow and in other operations.

Deputy Inspector-General of Hospitals Robert Hay, of the Royal Naval Hospital, Bermuda, on Dec. 2nd, aged 58 years. He became surgeon in 1863, staff-surgeon in 1877, fleet-surgeon in 1883, and attained the rank of deputy inspector-general in 1894.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on Jan. 9th, Inspector-General W. H. Lloyd in the chair, the sum of £70 was distributed among the several applicants.

HOSPITAL ABUSE AT DUBLIN.

(FROM OUR SPECIAL COMMISSIONER.)

SOME members of the medical staff of the Children's Hospital, Temple-street, Dublin, have recently resigned because new rules and regulations have been imposed "to which no self-respecting member of the profession can submit." Such, at least, are the words used by the medical men concerned, and on inquiry these terms seem to be fully justifiable. The hospital in question was founded in 1872, and, as usual under the circumstances, was governed by a managing committee on which the medical staff was represented. The members of the medical staff were appointed for five years, with the right of being re-elected. This rule, however, was never applied. At the expiration of the five years no re-election took place: all the members of the medical staff continued in attendance. Thus from the very beginning a precedent was established by which this rule was left in abeyance. For instance, the actual senior consulting physician has been on the staff of the hospital since its foundation and yet he has never been formally re-elected. That the rule in regard to such re-elections should have remained in abeyance is perhaps to be regretted. There is a feeling in various parts of the country that hospital staffs should be changed more frequently; that there is a tendency to monopolise such appointments, and this deprives the younger members of the profession of chances of advancement. However this may be, that is not the point in dispute; and, in regard to the present difficulty, it is only necessary to bear in mind that, whether wisely or not, it has not been the custom at this particular hospital to re-elect the members of the medical and surgical staff. Of far greater importance, especially to the general public, is the fact that, when first established, the Dublin Children's Hospital was declared to be an unsectarian institution. Subscriptions were obtained from Protestants as well as from Roman Catholics; and, this being the case, the Corporation of Dublin was justified in voting a subvention to the hospital. It is true that no Protestant was appointed on the medical or surgical staff; but this might have been explained on the ground that Roman Catholics are in the majority and did not necessarily imply a spirit of sectarian intolerance.

In the course of time, however, a Roman Catholic congregation known as the Order of the Sisters of Charity took over the entire management of the hospital. It is difficult to understand how this can possibly have been done. Undoubtedly the subscribers are themselves not free from blame or they would not have quietly submitted to such an act of usurpation. Having once succeeded in their *coup d'état*, the sisters proceeded to govern the hospital as absolute autocrats, and one of their first acts was to silence the medical staff, which had no longer a voice on the board of management, for this board was abolished. The subscribers were also treated in an equally cavalier manner and they have now nothing whatsoever to say in regard to the management and control of the hospital. Further, these sisters have actually taken upon themselves the responsibility of appointing medical men to the staff whenever a vacancy occurred. Yet there is no guarantee that they possess the technical knowledge necessary for such a selection. But if they possess no technical knowledge, and if they have usurped their functions, one thing is very certain—they possess very great influence and power of patronage. Thus it required more than ordinary moral courage, and perhaps also independent means of existence, for a medical man to venture upon a protest. Like the original founders of the hospital, the sisters also established a rule for the appointment of the staff, which they likewise failed to enforce. The sisters' rule was that the members of the medical and surgical staff

should be appointed for three instead of five years as formerly, but it was generally understood that this was a mere matter of form, and that the question of re-appointments would not be raised. As a matter of fact, this question was not brought forward till quite recently, and some of the members of the staff have held appointments under this three years' rule now for six years, and the question of their re-appointment was not raised at the termination of the first three years. Thus it is claimed that the medical staff are justified in considering that this rule is in abeyance.

What with the apathy of the subscribers, the ignorance of the general public as to what was going on, and the timidity of the members of the profession, who stand in terror before the sisters lest a boycott should be organised against them, things might have gone on peacefully for some time longer. Recently, however, a difficulty arose between the sisters and the nursing staff. Members of the medical staff protested that a nurse had been unfairly treated; but the sisters will brook no criticism. Their ideal is passive obedience, so on Nov. 4th last the superioress of the sisters of charity in charge of the hospital wrote to the honorary secretary of the medical staff to the effect that "all members of the staff held their posts at the will of the sisters of charity," and that if they wished to be re-appointed it would be necessary for them to sign the following form:—

"I hereby accept the office of —— in the Children's Hospital for a period of three years from (date), and I undertake to fulfil the duties of that office and to hold it only as long as I comply with the rules and regulations made from time to time by the sisters of charity, who are the governing body of this hospital."

The medical staff on receipt of this letter naturally objected to the enforcement of limited terms of appointment, and this for the reasons explained above. But, and this is far more important, they saw in the sudden enforcement of a rule which had been in abeyance ever since the existence of the hospital a deliberate act of intimidation. They concluded that this was an attempt directed against the independent discharge of their duties to the patients. It was also an attempt to make the medical staff recognise in writing that the sisters were the governing body of the hospital and that they had a right to establish rules and regulations for the government of the medical staff. Thus, if at any time the subscribers entered a protest and claimed their right to control, the medical staff, as well as the sisters, would be compromised in the act of usurpation. But the sisters were careful not to give the medical staff time to consider fully their position and responsibilities. The letter of the superioress was written on a Saturday, and it was expressly stated that the answer must be forthcoming on the following Tuesday. The staff unanimously protested. So far there was no division of opinion; but when it came to the question of acting up to the opinions expressed only two members of the medical staff had the courage to refuse their signatures and to resign. These two physicians, who hold eminent positions in Dublin, were thereupon replaced by two junior physicians who are engaged in club practice. The members of the surgical staff submitted and signed the declaration imposed upon them by the sisters.

The matter will not rest here. The nurse whom the medical staff tried to shield from what appeared to be an act of gross injustice will probably take legal proceedings and the whole of this scandal will be laid bare. Then, perhaps, the subscribers will want to know what has been done with their money and how far the promise that the hospital should be unsectarian has been kept. But if the subscribers with whose money a hospital is brought into existence and maintained have an undoubted right to control the expenditure, the medical staff who subscribe in kind, by reason of the work they do, have an equal right to a voice in the management. The union of the East London and suburban medical practitioners have a rule, which they have been able to enforce in at least one instance, to the effect that 25 per cent. of the seats on the board of management of hospitals should be occupied by members of the medical staff of the hospital. Evidently the Dublin practitioners should also form a union by which they could obtain not merely proper representation on the management boards of the hospitals, but they would have an organisation to protect them against the mortal terror of the boycott which seems to paralyse individual members of the profession. While it is thus imperatively necessary that medical men should act in this manner if they mean to maintain their individual independence and the dignity of their profession the public at large should also insist on their rights. It is not only the subscribers to the Children's Hospital who have just cause of complaint, but every ratepayer in Dublin has a right to know what is being done in their hospitals. The Dublin Corporation subsidises this hospital, that is to say, it gives the ratepayers' money to the hospital, and the ratepayers comprise persons of all denominations, Christians and non-Christians, Jews and Protestants, as well as Roman Catholics. If the latter want a hospital to be controlled solely by the Order of the Sisters of Charity then let them collect the money required from Roman Catholics only and not accept grants from the public funds or subscriptions from Protestants. And, again, whatever respect may be due to the sisters of charity for the good work which they attempt to perform, what technical qualifications do they possess that they should take upon themselves the management of a hospital? What right have they to impose rules on the medical staff which in some instances are, in respect to the hours of attendance, very irksome? It may be objected that a lay board of management is not better informed technically, but that is precisely why the organised members of the profession have insisted that the medical staff, which is technically competent, should have a large share of representation on boards that manage hospitals. Then, again, if a lay board of management commits errors or wastes money—and this it must be acknowledged often occurs—they have at least a constitutional right to exist, they are elected by those who pay, and if matters are not properly managed the subscribers are free to elect other more skilful administrators. But the sisters of charity escape all control. They have, of course, their ecclesiastical superiors, but these latter do not represent the subscribers any more than do the sisters themselves, nor do they possess any better technical qualifications. Under such a system, screened as it is from all public control, investigation, or criticism, every form of abuse is possible. And this cuts both ways; for, if abuse can be committed and escape detection, it is also possible that accusations of abuse may be brought forward which are false, but the secrecy of procedure renders an effective defence or refutation difficult. However, it is not necessary to insist that experience has proved that publicity is the best guarantee of purity; and any attempt to usurp functions and to escape from criticism is quite contrary to the spirit of the age.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Special Training for Officers of the Indian Medical Service.—Infected Plague Areas in India.—The Progress of the Epidemic.—The General Mortality of Bombay and Calcutta.

WITH a view to securing a succession of officers highly trained in bacteriological work the Government of India, with the concurrence of the Secretary of State, has decided that a selected officer of the Indian Medical Service shall always be attached to the medical school at Netley for the purpose of undergoing training. The selection will ordinarily be limited to officers who have completed the prescribed time of military duty, and while on furlough have devoted at least a year to the systematic study of bacteriology and pathology or bacteriology and hygiene in a recognised school in Great Britain or on the Continent, and the selected officer will be attached to the Netley Medical School for one year, to be extended under certain circumstances to two years during which he will be granted extra leave, which will count as service in India on the pay and allowances admissible to him on ordinary furlough, and he will retain a lien on his Indian appointment.

A highly interesting experiment on the lines of Major R. Ross's investigations into the question of mosquitoes and malaria is about to be tried in Calcutta. Mr. J. Nield Cook has suggested to the chairman of the municipality that two men should be employed in Calcutta and the neighbourhood, under the supervision of a health officer, to hunt out the breeding-places of anopheles claviger, or the malaria mosquito, and destroy the larvæ with kerosene oil or permanganate of potash.

The following areas in India are still declared as plague infected:—(1) the Bombay Presidency, including Sind; (2) the Bellary, Salem, and Coimbatore districts of Madras;

(3) Calcutta and the Saran and Howrah districts of Bengal; (4) the Nagpur division of the Central Provinces; (5) the Mysore State, including Bangalore; (6) the Hyderabad State; and (7) the Hoshiapur district of the Punjab. Plague mortality is going up slightly in Bombay city and a slight recrudescence is reported in the Jullunder district of the Punjab, but everywhere else in India it continues to decrease. The total number of deaths from plague during the week ending Dec. 2nd was 1576, against 1946 in the preceding seven days. Calcutta returns 56 deaths, Saran district 13 cases and two deaths, Bombay city 159 deaths, Karachi two deaths, the rest of the Bombay Presidency 1159 deaths, Madras Presidency 10 deaths, the Punjab nine deaths, the Central Province 16 deaths, and Mysore State 166 deaths. In Bombay city, however, while the official returns indicate but a slight increase of plague the general mortality has been rising rapidly and ominously. There has been a rise of 90 deaths during the past week—viz., from 959 to 1049. The average weekly mortality is about 600. It is curious to note that last year plague became epidemic (100 deaths a week) in the third week of November. Nearly the same thing occurred again this year, the week's record being 135. An unusual occurrence at this time of the year is the prevalence of measles and small-pox, but these only account for 18 and 15 deaths respectively. Dysentery and diarrhœa account for some of the increased mortality, but it is tolerably certain that undiscovered plague is responsible for the greater part.

In Calcutta also there has been an ominous rise in the general mortality but the number of deaths from plague reported continues about the same. The death-rate is 37 1 per 1000 per annum against, 34 7, the mean of five years. Attempts are made in the local press to throw doubt on the existence of plague and to question the returns of the plague staff. It is true that comparatively few cases are seen during life but investigations indicate approximately the amount which still continues. There is a tendency everywhere to conceal deaths from plague. In addition to the deaths returned as due to plague there still continue to be a large number of suspected cases.

The long-disputed question about typhoid fever affecting the natives of India is almost settled. More exact observations than were formerly taken show that the disease, although not nearly so common as in the European population, does nevertheless exist among them. I pointed out some time ago that the disease is not only milder in character, but is characterised by the less-marked development of abdominal symptoms. It is very probable that typhoid fever has been in existence in India for very many centuries and that a great evolutional immunity has been effected by the elimination of those susceptible to it. This question of racial immunity by previous experience applies probably to nearly all diseases, and I have also previously pointed out the mortality and incidence of certain diseases affecting the British as compared with the native troops to illustrate this argument. The reports of the younger medical officers of the Indian Medical Service indicate that enteric fever is more common than is generally supposed while the senior officers seem to think it very rare or almost unknown. In this connexion it is interesting to note the large number of deaths which take place in a city like Calcutta after from 15 to 30 or more days of fever. Few of these cases come under accurate observation and when they do they are generally labeled remittent fever. The statistics of the gaols of India show 21 cases of enteric fever with seven deaths for 1896, and 34 cases with 15 deaths for 1897. As these cases have all been verified by post-mortem examination the figures are particularly trustworthy. They are undoubtedly very small compared with the immense gaol population, but then it is probable that a large number of mild cases passed unrecognised. The same thing applies to men serving in the native army.

Calcutta, Dec. 14th, 1893.

NEWPORT WATERWORKS.—The total expenditure by the Newport (Mon.) Corporation on the Wentwood Waterworks Scheme up to the present has been £188,508.

VACCINATION FEES.—At the meeting of the Tetbury Board of Guardians held on Jan. 3rd it was decided that the public vaccinator (Mr. W. Wickham) should receive 5*s*. for each successful vaccination in Tetbury and 7*s*. 6*d*. in rural parishes.

Correspondence.

"Audi alteram partem."

THE LATE SIR JAMES PAGET.

To the Editors of THE LANCET.

SIRS,—You have alluded to the great consideration which Sir James Paget always displayed towards those whom he met in consultation. Many years ago an instructive illustration of this came under my notice. I was seeing a patient suffering from, I think, some form of paralysis, but without any "surgical" feature, with an old practitioner in a southern suburb. He said that a month before he had got Sir James Paget to see the patient with him, and added in a half-apologetic way, "I always call in Paget whenever I can, because I know that, whatever the case is, the patient is safe and I am safe."—I am, Sirs, yours faithfully,

Queen Anne-street, Jan. 5th, 1900. W. R. GOWERS.

BORIC ACID IN FOOD.

To the Editors of THE LANCET.

SIRS,—Dr. Liebreich, in THE LANCET of Jan. 6th, makes a communication in which he assumes that an erroneous conclusion was arrived at in attributing serious illness to five individuals and the death of five fowls to the use of boric acid, which had been added as a preservative to the food consumed. Dr. Liebreich's assumption is based upon an experiment of giving boric acid in definite quantities to eight fowls without the manifestation of illness amongst them. In a subsequent paragraph, however, when criticising Dr. Annett's investigations, he says, in reference to the same: "All that these experiments prove is already known—viz., that animals finally succumb under the repetition of large doses."

Now this admission utterly destroys the value of Dr. Liebreich's experiment for the purpose of argumentative disproof of the toxic effects of boric acid in the cases I narrated. "Large doses" were unintentionally given in the preservative added to the food, and, further, the fowls that took most died, whilst those which devoured less recovered. But Dr. Liebreich himself evidently does not consider his experiment sufficiently convincing, because he has recourse to various suggestions to account for the results otherwise than by boric acid. In reference to some of these suggestions I may say that although the symptoms were very typical of poisoning by large doses of boric acid, including suppression of urine, &c., the desirability of considering other causes was not overlooked, and amongst other poisons, one of the most likely toxic bodies to be present in milk—viz., tyroxicon—was especially searched for but with negative results. On the other hand, large quantities of boric acid were found by the borough analyst in the crop and gizzard of one of the fowls. Boric acid was also found in the milk supplied by the dairyman and in the glacialene which the cook added to the milk. Add these facts to the admission of Dr. Liebreich—viz., "That it is known that large doses prove fatal to animals"—and I fail to perceive the error with which Dr. Liebreich taxes me. I ought to add, as Dr. Liebreich refers to vanilla, that this flavouring agent was used by the cook, but I am unaware of any poisonous effects which have been traced to this article when supplied in a pure state. With regard to "alarming the world," I sent no communication to the lay press on the subject, but simply brought the question before a meeting of the East Kent Medical Society for discussion and put the facts on record in my annual report. I trust that Dr. Liebreich does not attribute to me any desire for sensational publicity.

I am, Sirs, yours faithfully,

M. K. ROBINSON, M.D Erlang.,

Dover, Jan. 9th, 1900. Medical Officer of Health, East Kent.

"A CASE OF HÆMORRHAGIC ASCITES."

To the Editors of THE LANCET.

SIRS,—Since writing the account of the case which appeared in THE LANCET of Jan. 6th (p. 17) under this title there has been a case in the post-mortem room of the Bristol Royal Infirmary which presented some similar features. No

ascites was present, but there was intense congestion of the intestines over precisely the same area—that is to say, all the small intestine below the duodenum was affected, together with the ascending colon. The duodenum, the transverse colon, and the large intestine below it were quite free from congestion. Hæmorrhage had taken place into the small intestine, but the fæces in the large intestine were not mixed with blood. The veins of the mesentery were not distended as in the former case. The superior mesenteric vein and artery were free from all trace of ante-mortem thrombosis. The other abdominal organs were quite healthy, but the lymphatic glands in the mesentery were much enlarged. The heart and lungs were healthy. The case was that of a boy, aged four years, who was twice admitted under the care of Dr. Shaw during the space of three weeks. On the first occasion there was considerable abdominal distension with constipation. At the end of about a week, however, he left the infirmary apparently quite well, but was re-admitted three days before death complaining of pain in the back and in the abdomen. The facial expression was that of great collapse. He vomited occasionally, and the bowels were obstinately constipated, but the abdominal distension had not returned. The bowels had not been moved at the time of death.

As already mentioned, the area of congestion of the intestines was precisely the same in both instances. Although in both the congestion in great measure corresponded to the distribution of the mesenteric artery and vein, it did not do so absolutely, since in neither case the transverse colon showed congestion. The absence of thrombosis in the second case is interesting and suggests that the thrombosis in the small vessels of the liver in the first case was of secondary importance. Dr. H. D. Rolleston[1] refers to cases of intestinal hæmorrhage which suggest vascular occlusion, yet no such blockage can be found. He considers that these cases are possibly allied to the peritoneal sanguineous cysts, records of several cases of which I have collected and published in the Guy's Hospital Reports.

I am, Sirs, yours faithfully,

THEODORE FISHER.

"SOME POINTS IN LIFE ASSURANCE EXAMINATIONS."

To the Editors of THE LANCET.

SIRS,—I am glad to see from the letter by Dr. H. Crosby in THE LANCET of Dec. 30th, 1899, that he can name some few life assurance companies which have a question directly bearing upon suppurative ear disease. I was not unaware that a certain proportion paid attention to this detail. Those, however, who read my communication in THE LANCET of Dec. 16th will have seen that my chief point was the absence of any question regarding the temperature, whereas all offices require definite information regarding the pulse-rate. In the cases I quoted it was the slight rise in temperature which led me to postpone them, when in the one case suppurative ear trouble (fatal 10 days later) was discovered and in the other incipient phthisis. I am unaware of any company having a question printed regarding temperature, an omission which, in my humble opinion, is of vital importance. I am, Sirs, yours faithfully,

FRANCIS TAYLOR SIMSON.

Northumberland-avenue, W.C., Jan. 8th.

DIPHTHERIA AND MILK-SUPPLY: A FILTHY HABIT.

To the Editors of THE LANCET.

SIRS,—We all from time to time meet with cases of diphtheria where there seems complete proof that the infection has been conveyed by means of milk. In many cases where no association of the milk with a case of diphtheria can be proved this is attributed to infection from a disease in the cow caused by the same organism as human diphtheria. It seems to me possible that a habit I have noticed among milkers in country places may in many cases offer a simpler solution of the problem. Recent research has brought to light the fact that a micro-organism not to be distinguished from the Klebs-Löffler bacillus is to be found inhabiting the throats of many persons apparently in their usual health and pursuing their usual avocations. Old-fashioned milkers, specially old yardmen in country places, often moisten their hands with saliva before seizing the teats instead of moistening them with the first drawn drops of milk. It seems to me more than probable that by this means the bacillus of diphtheria may be conveyed from the throat of the milker to the milk. My attention was first drawn to this habit about two years ago on a farm in the East of England where an old yardman when giving me a lesson in milking directed me to begin operations thus. I have since found that this is quite a common custom, though it may be omitted when a visitor is present at the milking. I have never seen this point touched on, though it seems to me worthy of some attention. We are at this present time apt always to look to disease in the cow as the source of infection, though the connexion between disease in the cow and these cases of milk-borne diphtheria is often far from clear.

I am, Sirs, yours faithfully,

ETHEL M. N. WILLIAMS, M.D. Lond., D.P.H. Cantab.

Newcastle-upon-Tyne, Dec. 27th, 1899.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 4th, 1899, p. 1227, appears an article by Dr. J. M. Atkinson and Mr. J. Bell giving details of two cases of death under chloroform which seems to call for remark. It will scarcely be disputed that these deaths were not merely accidental concomitants of chloroform administration, but were actually due to the drug, in the sense that they would not have occurred had not chloroform been given. The points of interest appear to fall into two groups—first, those connected with the method of administration, and secondly, those connected with the cause of death. The instrument of administration was in one case a Krohne and Sesemann's inhaler and in the other a Skinner's mask. It is to the use of the former that I wish to draw attention particularly. Two deaths have recently been reported in THE LANCET as occurring when chloroform was given through this inhaler, and Dr. James Edmunds has in recent numbers written on the subject pointing out that it is perfectly easy to kill a man with chloroform out of a Krohne's inhaler. It cannot be too strongly insisted on that by no merely mechanical means can chloroform be given with safety.

A Krohne's inhaler seems to have this advantage—that the wastage of chloroform is minimal, so that most of the choloroform evaporated is absorbed into the circulation, and as a result of this the amount circulating in the blood is fairly accurately known. But to give chloroform or any other drug with safety one wants to know not the amount circulating in the blood but the effect which it is having on the tissues. Accurate dosage does not obviate the necessity of looking carefully for symptoms of danger resultant on the administration of the drug, symptoms which will arise with whatever accuracy of dosage the drug is given. In one of the cases under consideration the very use of the inhaler seems to have introduce a new element of danger. We are told that the patient gasped, the inhaler was removed, and she was discovered to be cyanosed. It cannot be doubted that the cyanosis had not been produced that instant, but the inhaler seems to have covered the face so that the cyanosis escaped notice till it was too late to combat it. If the use of the inhaler means any relaxation of vigilance in the search for symptoms of danger, it can do nothing but incalculable harm, and at its best it is little more than an economiser of chloroform.

As regards the cause of death in these two cases, as is usual the immediate impulse is to fix on the heart as the organ primarily implicated. In one case the opinion is definitely formulated that "the cause of death ..... appears to have been due to the action of chloroform on the cardiac ganglia paralysing them, they being in an abnormal state of susceptibility from some undefined cause"—an opinion for which there is not the slightest shred of evidence adduced. In the other case the report shows that the mind turned to the possibility of fatty degeneration of the heart, but this was found to be absent. Yet in both of these cases the description brings out strongly a common symptom pointing to the respiration as the means by which death was produced—I refer to cyanosis. Can cyanosis ever be compatible with primary heart failure? What does cyanosis mean but that capillaries and venules are distended with deoxygenated blood? If the heart fails primarily how can it drive the

[1] System of Medicine, Allbutt, vol. iii., p. 715.

blood into the capillaries and veins with sufficient force to distend them? The cardinal sign of heart failure is pallor due to the capillaries and veins being empty owing to the heart's beat not being sufficiently powerful to drive blood into them. Cyanosis means a heart of some vigour and is incompatible with primary heart failure. In these cases of death under chloroform I know of no cause for cyanosis other than obstructed respiration. In both of these cases the first sign of danger noticed was abnormal respiration and the patients ied from asphyxia. Obstructed respiration or asphyxia has its well-known stages—the stage of cyanosis or strongly beating heart and the stage of pallor or heart failure. If one considers that in asphyxia death occurs from heart failure, then one may consistently say that that was the event in these cases. The conditions are identical. Still, in both stages if the initial obstruction can be prevented death will not occur. The lessons to be learnt from these two deaths under chloroform are the usual ones: first, not to give chloroform by rule of thumb whether through an inhaler or not, but to be guided entirely by the symptoms produced; and, secondly, to keep the respiration normal both as regards regularity and free air entry. With these precautions chloroform may be given with safety.—I am, Sirs, yours faithfully.

CLAYTON LANE, M.D. Lond.,
Lieutenant, I.M.S.,

Camp Grinburn, Mishmi Field Force, Dec. 8th, 1899.

SICK AND WOUNDED OFFICERS' SURGICAL AND MEDICAL AID FUND.

To the Editors of THE LANCET.

SIRS,—I shall be glad to be afforded the opportunity of making an appeal in your columns on behalf of those sick and wounded officers of all services whose means are inadequate to secure that efficient medical and surgical treatment which will often be needed to restore to them, after their return home, the health they have sacrificed in the service of their country.

Amongst the great number of officers who have unhappily been wounded or are suffering from disease contracted on service there will certainly be many who have small private means, and who are not in a position to command the skilled assistance they will urgently need. In many cases continuous treatment for long periods will be necessary. Though to offer assistance in such cases will be a matter of considerable delicacy, nevertheless, I feel sure that it will be generally felt that an attempt should be made to do so.

The undermentioned gentlemen have consented to act upon a General Committee, and to assist the objects of the scheme in every way within their power.

A fund has been opened to which I earnestly trust many of your readers will readily contribute. The provision of accommodation for convalescent patients is a part of our scheme, and I have already received several offers from private persons which I have no doubt that the Committee will be glad to entertain.

Subscriptions may be sent to Messrs. Coutts, Strand, London; the Duke of Abercorn, Hampden House, Green-street, W.; or to the Hon. Arthur Brodrick, 18, Eaton-square, S.W. (Hon. Secretary and Treasurer to the Fund, to whom enquiries may be addressed). Cheques should be crossed "Sick and Wounded Officers' Surgical and Medical Aid Fund." I am, Sirs, yours faithfully,

ABERCORN.

Hampden House, 61, Green-street, W., Jan. 11th, 1900.

"THE CONFERENCE AT NEWCASTLE AND THE MIDWIFERY QUESTION."

To the Editors of THE LANCET.

SIRS,—I cannot hope to satisfy the craving of Mr. Haydn Brown's forensic appetite but would like to lay before him the following points arising from his letter—points which I put forward eight or nine years ago and to which I have yet seen no satisfactory solution. Provided that every confinement case is to be once visited by a medical man, would the medical man be willing to go? It would mean an enormous increase in midwifery practice, a branch of practice which, as has been often pointed out, a very large proportion of men encourage as little as possible; it would mean being disturbed three or four nights for every one on which we are at present called out to a confinement. If going was a matter of choice many, in the country at any rate, would, I am sure, refuse. And could it be made compulsory, in either event how is the medical man to be paid? Then—and this to my mind is the chief objection to the proposal as made by Mr. Haydn Brown—would any practitioner care to accept the responsibility which would attach to him after visiting a confinement just once and in any stage? The responsibility for the safe conduct of the whole

case would certainly be transferred from the nurse to the medical man as soon as he had seen the patient; it may be wrong that it should, but I have no doubt but that it would, and this loss of responsibility by the nurse would react dangerously on her. Having sent for the medical man quite early in a case and he having pronounced all well, what responsibility would she feel for any untoward accident afterwards? Again, suppose, for instance, a fragment of placenta to be retained without the nurse knowing it, and that the medical man does not see the case until labour is presumed to be complete, of what good can his visit be and who will be held responsible when the patient develops septicæmia? Why, the medical man, of course. I cannot but think that the proposal for a visit from a medical man in every case and at any time the nurse may choose would shift responsibility from the very place where we want to place it. The suggestion in the Bill of the British Medical Association that the nurse should send when she thinks it necessary and on certain specified occasions appears to me to meet the case much more effectually.

I am, Sirs, yours faithfully,

Freshford, Jan. 8th, 1900. CHAS. E. S. FLEMMING.

THE UNIVERSITY OF LONDON ELECTION: THE CANDIDATURE OF DR. W. J. COLLINS.

To the Editors of THE LANCET.

SIRS,—In the unforeseen elevation of Sir John Lubbock to the peerage and with the possibility of the election caused thereby being rushed before Parliament meets, it is well that the medical graduates should consider carefully the claims of the two candidates who have already taken the field and between whom the running may possibly alone lie. In view of the large proportion which the medical bear to the non-medical graduates of the University, it would not be at all unreasonable that they should claim to be represented by one of their own body, and if a strong medical graduate, against whom no objection might lie, were put forward, he would probably receive the unanimous support of his fellow-graduates.

Of the two candidates referred to, one, Dr. W. J. Collins, is undoubtedly a strong one. He had a distinguished collegiate career and he has since shown administrative capabilities of the highest order. But he lies under the objection of having supported the anti-vaccination movement in a way which makes it very difficult to absolve his intelligence except at the expense of more necessary attributes. If his identification with anti-vaccination had been confined to his connexion for some years with the London Anti-Vaccination Society as one of its vice-presidents, and if it had ceased with the publication of the dissentient statement of himself and Mr. Picton in the report of the Royal Commissioners, his fellow graduates might perhaps have felt disposed to condone it. But it has not done so. From that time to this he has allowed himself to be put forward by the pamphleteers and letter-writers of the Anti-Vaccination League as one of the leading champions of their cult and as lending the mantle of his authority to the most preposterous mis-statements. And although he has been formally invited to dissociate himself from such a use of his name he has not thought fit to do so. He may assert, as he did at one of the meetings of the Anti-Vaccination Conference at Leicester in October last, that "he has never accepted the appellation of anti-vaccinator." But a man is known not only by the name he accepts but by the company he keeps. And when Dr. Collins is content to stand on the same platform, as he did at Leicester, with another member of his own profession who did not scruple to say that "the medical power of the Local Government Board" had been responsible for "one of the most damnable scenes that had ever been enacted in England, where the sanctity of the English home was invaded and where the wife's honour was sought to be taken away ..... in order that the glory of vaccination might be upheld," he will have some difficulty in persuading most people that he is not very unfortunate in the company he keeps whether he be an anti-vaccinator or not.

One of Dr. Collins's nominators is the editor of the *Vaccination Inquirer*, the organ of the Anti-Vaccination League.

I am, Sirs, yours faithfully,

Jan. 8th, 1900. A LONDON GRADUATE.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Christmas Festivities.

THERE has been no lack of the usual entertainments and festivities at the various hospitals in the city during this season. The staffs of the different institutions have thrown themselves with enthusiasm into the task of making the patients happier and brighter during their stay in hospital. On all sides their efforts have met with hearty and appreciative response and the settling down to every-day routine will be associated with many pleasant memories. An attraction at the General Hospital on Jan. 7th was the visit of the Chinese Ambassador, Sir Chihchen Lofengluh, accompanied by his suite. His Excellency expressed himself in good English and stated the pleasure which it had been to him to see how the patients were cared for and his admiration of the voluntary system which did such valuable work.

Deaths under Chloroform.

Two deaths under anæsthetics have recently been the subjects of inquiry by the city coroner. The first occurred at the General Hospital in the case of a child who was operated upon for hernia. The operation was completed when it was observed that the breathing had stopped, and all attempts to restore it were futile. Chloroform had been used. The second was that of a man, aged 61 years, a patient at the Queen's Hospital, the operation being for cancer of the jaw. The necropsy showed that death was due to asphyxia caused by collapse of the left lung. At the commencement ether and chloroform mixture was used and subsequently chloroform alone, the operation being necessarily a prolonged one.

Typhoid Fever.

Typhoid fever still continues to be rife. The number of cases increases daily. Indeed, since 1890 the number has almost trebled per annum. Various causes are assigned; no doubt sanitary defects and climatic influences have something to do in the way of factors. Under the auspices of the health committee of the city council Dr. C. K. Millard lectured on Jan. 5th on the Prevention of Infectious Diseases. The spread of knowledge by this form of teaching appeals to the intelligent and better-educated class of citizens, but it is hardly among these that the practical application is required.

Jan. 9th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Edinburgh.

FROM the annual report of the University of Edinburgh it is seen that the total number of matriculated students during the past year was 2848; of these 1399 were enrolled in the Faculty of Medicine. The number of women attending extra-academical lectures with a view to graduation in medicine in the University was 85. The General Council of the University now numbers 8667. The total annual value of the University fellowships, scholarships, bursaries, and prizes now amounts to about £17,790. Of this sum £3500 is awarded in the Faculty of Medicine. A number of bursaries are in the gift of patrons, but the great majority of the University bursaries, prizes, &c., are awarded by the Senatus after competitive examination. In addition to the above sum a sum of upwards of £600, the income of the Earl of Moray Endowment Fund, is available annually for the encouragement of original research. Two new lectureships have been inaugurated during the year, the lecturers being Dr. Andrew Davidson, lecturer on diseases of tropical climates, and Dr. Allan Jamieson, lecturer on diseases of the skin. Dr. J. W. Ballantyne has been appointed for one year University lecturer on teratology and ante-natal pathology, and is to deliver his course of lectures in February. Two vacancies in the professoriate occurred during the year by the death of Professor Rutherford and by the resignation of Professor Prothero. The chair of Physiology has been filled by the appointment of Professor Albert Edward Schafer, of University College, London, while Professor Richard Lodge of the University of

Glasgow has been appointed to the chair of History. The John Usher Institute of Public Health is now in course of erection at Warrender Park.

"Nordrach-on-Dee."

A portion of ground 25 acres in extent has been purchased by the promoters of the proposed sanatorium for consumptives on Corsee Hill, Banchory. The price paid for the ground, which is the property of Sir Thomas Burnett of Crathes, is between £5000 and £6000. Building operations are to commence almost immediately. The building is estimated to cost £12,000.

Scottish Poor-law Medical Officers' Association.

In the annual report of the Scottish Poor-law Medical Officers' Association reference is made to several questions which came before Parliament last year, regret being expressed that the Association's Bill to amend the Local Government (Scotland) Act, 1894, introduced by Mr. Alexander Cross, M.P., was unfortunate in the ballot and never got the chance of a second reading. The Bill introduced by Mr. D. N. Nicol, M.P., suffered in the same way. Mr. Cross has again agreed to introduce the Bill of the Association next session. Dealing with the case of Mr. Lamont of South Uist, which has been often mentioned in THE LANCET, the report calls attention to Mr. Balfour's acknowledgment that if Scottish Poor-law medical officers had a power of appeal to the Local Government Board such a case as that of Mr. Lamont could not possibly have occurred. Questions in regard to tenure of office have also engaged the attention of the Association and have been brought by it before the British Medical Association. Sir Charles Cameron, M.P., has consented to become Honorary President for 1900. The annual meeting and dinner of the Association will be held at 36, Buchanan-street, Glasgow, on Jan. 19th. The secretary of the Association is Mr. W. L. Muir, 1, Seton-terrace, Glasgow.

The late Dr. George Elder.

Dr. George Elder, who died at his residence in Leopold-place, Edinburgh, on Jan. 6th, had a distinguished career as a student at the University and much might have been expected of him had his life been spared. He graduated as M.B., C.M. Edin., with honours, in 1891 and also gained one of the Vans Dunlop Scholarships of £100 per annum tenable for three years. In 1896 he took his M.D. degree and was also admitted a Fellow of the Royal College of Physicians of Edinburgh. At the time of his death he held the appointments of clinical tutor in the Royal Infirmary, assistant physician to Leith Hospital, and physician to the New Town Dispensary. Dr. Elder, who was only in his thirtieth year, was a native of the parish of Carnwath in Lanarkshire. He had contributed several articles to periodical medical literature.

Jan. 10th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Death-rate of Dublin.

THE death-rate of Dublin for the week ending Jan. 6th was exceptionally high, reaching 51 per 1000. The usual rate of 33 is so high by comparison with that of some cities that the increase to 51·3 may be regarded perhaps as an accidental exacerbation similar to that just now being experienced by London, but whatever the reason the figures can only be regarded as appalling.

Royal College of Physicians of Ireland.

It is announced that the sixth award of the triennial Reuben Harvey Memorial Prize will be made early in July, 1900. The prize is open to all students of the various schools of medicine in Dublin, and also to graduates or licentiates of these bodies of not more than three years' standing at the time of the award. The prize, value £25, will be awarded to the writer of the best Essay on Animal Physiology and Pathology. The essays, bearing fictitious signatures, are to be lodged with the Registrar of the Royal College of Physicians of Ireland, 6, Kildare-street, Dublin, on or before June 1st, 1900.

The Belfast Workhouse.

At the usual weekly meeting of the Belfast Guardians on Dec. 19th one of the members spoke of the horrible system of blackmail practised in the wards where wardswomen were in charge. He alleged a case in point where a young lad who was suffering from rheumatic fever was visited by his mother, and when she retired the woman in charge of the ward asked him if his mother had left anything for her. On his replying in the negative she abused him with bad language and, what was worse, deprived him of half his allowance of milk. The chairman asked that the matter should be left to the infirmary committee to deal with. It appears that there are over 600 able-bodied men and women in the workhouse and, as one of the Belfast daily papers points out, information is wanted as to the age, sex, and length of residence of these people. What is the cost of their keep and what is the value of their work? The present system is a wretched one, which stereotypes these able-bodied workers as a burden on the rates and it leads to patients being placed at the mercy of harpies like the wardswoman referred to. Her only punishment, if she can be identified, is to send her to the body of the house. The Poor-law system in Ireland is in a deplorable condition.

The Influenza.

Not since the early years of the present visitation of influenza has the malady been so widespread in Belfast and in the whole of the North of Ireland as it is now. Coincidently with this extraordinary recrudescence of the disease is the prevalence of the most variable and rapidly-changing weather. It does seem strange that after so many years' visitation of influenza we know so little as to the peculiar conditions which determine its assumption of an epidemic type as at present. Whole households are ill at once, business is being very much interfered with in Belfast owing to the illness of employés, and medical men are greatly overworked.

Extraordinary December Rainfall in Ulster.

The last month of 1899 has been a record one in Ulster in the amount of rainfall, for there was rain on 24 days, there being, in other words, only seven dry days. The total amount registered was 6·05 inches, and on one day (Dec. 28th) 1·21 inches fell. 1899 has been an exceptionally wet year, for 10·29 inches more of rain have fallen than in 1898, when the total rainfall registered was 33 07 inches.

Health of Belfast.

At a meeting of the Belfast Corporation on Jan. 3rd the general health of the city was reported to be good, the last monthly statement of the Registrar-General tabulating the death-rate of Belfast as 18 3 per 1000. The annual death-rate for 1899 was also the lowest upon record—viz , 22 per 1000. The epidemic of typhoid fever is practically over, there being only 54 cases notified in December. The chairman of the Public Health Committee, in his speech at the city council on Jan. 3rd attributed this subsidence of the enteric outbreak to the increased powers obtained by the water commissioners for preventing the pollution of the Belfast water-supply, and also to the energetic action of the Public Health Committee. With the introduction of the new Mourne water-supply he was confident that typhoid fever would become one of their rarest diseases. During the past three months 10 cases of small-pox have occurred. Owing to prompt measures being adopted the disease has not spread. The great want, the chairman said, was a proper hospital where such cases of small-pox, as well as suspicious cases, could be isolated. He was of opinion that at a very early date the corporation should construct a small-pox hospital at Purdysburn, as until this was done Belfast was not in a proper condition to resist a small-pox epidemic. Stringent efforts were being made to put cowsheds into good order and to improve the milk-supply of the city and to prevent the sale of milk affected in any way with tuberculosis. He hoped the rural authorities would combine with the city sanitary officials in this most important matter. New refuse destructors would shortly be in working order, and in a few years all the houses without proper accommodation would be provided with water-closets. During the past year 2734 new water-closets had been erected in old houses by the direction and under the supervision of the public health department. It is interesting to note that while the death-rate as compiled from the Registrar-General's returns for the three weeks ended Dec. 23rd is 18 3 per 1000 for Belfast, during the same period it was 41 5 in Dublin and 27·4 in Cork. The extraordinarily high death-rate of Dublin is attributed by Mr. T. W. Russell, M.P., to the overcrowding of the tenement houses.

Case of Anthrax.

An interesting case of anthrax is at present in one of Professor T. Sinclair's wards in the Belfast Royal Hospital. The patient, who is employed in a bone manure manufactory, came to hospital with a sore on the inner side of the left thigh. This consisted of a central depressed gangrenous patch, surrounded by a series of vesicles outside of which there was a corona of œdema. From the serum of the vesicles Dr. Lorrain Smith cultivated the anthrax bacillus. Professor Sinclair removed the local sore and the glands in Scarpa's triangle, which were enlarged, and tied the saphena vein. The glands fortunately only yielded on cultivation the staphylococcus bacillus, showing mere local irritation. The man has done well.

Portadown Water-supply.

A very influential deputation appeared before the Portadown Urban Council on Jan. 1st with a memorial signed by 1100 ratepayers in opposition to the proposed plan of taking the new water-supply from the river Bann. It would appear that a supply of water is an urgent necessity for Portadown and this can be obtained either from the river Bann or from Lough Neagh, into which the Bann flows. The commissioners asked Sir Charles Cameron to examine both supplies, and he did so, and reported that the water of the lake was superior to that of the river only in colour, being not so yellow. As the river source would be cheaper he reported in favour of it. He advised ample filtration with slow passage of the water through the filter beds. He reported that the Thames was subject to much more filtration than the Bann.' In this way the commissioners were guided in adopting the river source of supply. When arrangements as to plans are complete the commissioners will apply for a loan and this will lead to a Local Government Board inquiry.

Jan. 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Medical Officers for the Mercantile Marine.

A LAW passed in 1896 completely altered the organisation of the sanitary measures as hitherto existing in France and brought it into conformity with the decisions arrived at by the international conferences which had met at Venice, Dresden, and Paris. In addition to doing away with the vexatious system of quarantine and replacing it by strict sanitary inspection and a well-organised system of disinfection a special body of medical men for the mercantile marine was ordered to be set on foot. The steamship companies were to be obliged to have on board their boats a competent medical man selected from a list drawn up after a competitive examination in the pathology of foreign diseases, in bacteriology, in legal sanitary measures, and in methods for disinfection. The companies could choose their medical men from a list of those who had passed the examination, and such lists were posted at every port. Some companies were wise enough to see that if obedience to this order threw some slight extra expense upon them at the outset, yet that the presence of a duly authorised medical man would be of the greatest assistance to them in the event of an epidemic. Other companies, however, could not rise to this view and only looked at the extra expense, for before the passing of the regulations their boats only carried a medical student, who was paid a mere nominal salary or sometimes none, or else they carried no medical adviser at all. The regulations, therefore, were bitterly opposed by such as well as by those old practitioners who had been in the employ of the companies and who were either too old or too lazy to get up the knowledge required for the passing of the examination. The various Ministers of State concerned did nothing to stay the progress of the reform; the Minister of the Interior, under whom matters of public health come, agreed with the Minister of the Marine Department that a period of two years should be allowed for the new regulation to be duly made known to the service; but the Minister for Foreign Affairs, whose duty it was to notify the change to all consuls and agents concerned, was remiss in his duties. Dr. Reynés in an interesting article in the *Presse Médicale* quotes an instance as having occurred in the case of a Marseilles company which is in the habit of running boats to Genoa to pick up Italian emigrants who sail to America under the French flag. This company takes an Italian medical man as surgeon. The French consuls at Naples and Genoa who signed the ship's papers, and in so doing committed a breach of the regulations of 1896, have this excuse to offer, that they had never been officially informed of them. Dr. Reynés in his article makes a vigorous claim for the strict enforcement of the regulations as well as strict official recognition of the rights of these medical men who have to pass a very severe examination, who thereby gain what should be a privileged position but whose rights as a fact are merely nominally guaranteed. There are in all 250 of these mercantile marine medical men, of whom 150 form a society *de médecins sanitaires maritimes*, presided over by M. Borel and having its headquarters at Marseilles. It publishes a quarterly journal which deals with technical matters and professional interests. Dr. Reynés, who is Vice-President of the society, demands that the *médecins sanitaires maritimes* should be granted autonomy and independence. He is not satisfied that the medical man should be a simple servant of the company taken on and paid at the company's pleasure. If, for instance, the medical man should have to certify the existence of some disease in opposition to the interest of the company he has no liberty to speak out. If he is conscientious and certifies the case as suspicious he receives the formal congratulations of the Government and his *congé* from the company who fill his place with someone more complacent. This is a matter of considerable importance, for at present the medical man has to be very heroic when the question is one of either losing his place or neglecting his duty. Dr. Reynés demands that the medical man should be as much an agent of the State as are the post office officials on board, and that the company should have no right to dismiss him save, of course, in the event of his committing a grave breach of discipline while on board.

The Sale of Impure Ice.

The Prefect of Police is acting on the advice of the Council of Hygiene. The attention of the Council was drawn to the sale of impure ice by the occurrence, especially in summertime, of various gastro-intestinal affections, sometimes of an epidemic nature. These affections appeared to be due to the use of either natural ice collected from impure sources or of artificial ice made from dirty water. The Prefect of Police has decided that in future ice-sellers must stock and sell ice as being of two definitely distinct kinds. These must be distinguished by being ticketed as ice for eating purposes and ice for industrial purposes, and the former must be obtained from spring or sterilised water. In no case is the latter kind, which is not intended for internal consumption, to be substituted for the former under pain of a very heavy penalty.

The Disinfection of Telephones.

The Under-Secretary of State who is responsible for the posts and telegraphs, has, with a view to avoid the transmission of infectious diseases, just made an order that the receivers and transmitters of all public telephones shall be disinfected daily by being washed with a strong solution of carbolic acid. This concession to the principles of hygiene has been received with a certain amount of scepticism by medical men. The idea, they say, is excellent, but they take exception to the choice of a disinfectant, for carbolic acid has an abominable smell and is of very feeble microbicidal power.

Jan. 9th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

A Contre-coup to the "Holy Year."

FRESH from his successful vindication of Italian to a place among the languages officially recognised at the next International Congress of Medicine and Surgery, from his bidding godspeed to Professor Terni of Messina *en route* to Portugal and Brazil to make known the results of the intravenous injection of corrosive sublimate in pestis bubonica, and from his task of filling up 11 chairs left vacant in the University of Cagliari, the versatile and indefatigable Minister of Public Instruction has recently issued a circular designed as a corrective to the pro-Papal reaction supposed, rightly or wrongly, to be promoted by the celebration of the Holy Year. Recalling

the fact that the first Holy Year was instituted by Pope Boniface VIII. in 1300; that among those who repaired to Rome for the occasion was Dante Alighieri; that it was in that year the great Tuscan poet, profoundly impressed by the degeneracy of the age, conceived the Divina Commedia in which he laid the lines of that patriotic ideal which, after six centuries of vicissitude and struggle, has culminated in Italy's unity and independence,—Dr. Baccelli, in the circular aforesaid, invites all the schools and seats of learning throughout the kingdom to commemorate the opening year of the next century by special study of Dante with a view to wider academic competition on the many themes suggested by his poem—competition in which the successful candidates will receive prizes from the State on the award of its Department of Public Instruction. By the step thus taken Dr. Baccelli institutes a new jubilee—accepted by lay and clerical journals alike as a *contre-coup* to that of the Holy Year—and appeals to Young Italy to devote itself to the study of the national poem so as thereby to make itself proof against the Ultramontane influences arrayed on the side of the Vatican in antagonism to the work of Mazzini, Cavour, and Garibaldi. Without commenting on the political inspiration of the appeal the youth to whom it is addressed may safely be congratulated on the impulse thus imparted to the study of a poem which has always possessed the most powerful attraction, even fascination, for the liberally educated of every country, which in Germany and Great Britain has numbered among its interpreters and commentators members of all professions, including the medical, and which in the latter country alone can point to Dr. Barlow and to Dr. John Aitken Carlyle as quite *hors ligne* in knowledge of its tenour and in power to throw light on its obscurer passages. Always solicitous for the honour of the profession as compatible with the highest culture outside its special subject-matter, Dr. Baccelli, while taking what he holds to be a patriotic step against supposed obscurantism and reaction in Italy, is also proving once more that the most loyal devotion to the healing art and the sciences underlying it does not exclude appreciation of the *chefs-d'œuvre* of the human mind, whether these have come down to us from ancient or from mediæval times or whether they are inspired by the vicissitudes and the events of the day now passing.

Three Medical Worthies.

At Padua on Dec. 7th, at the ripe age of 86 years, died Lodovico Brunetti, emeritus professor of pathological anatomy. His was a striking personality, combining ardent prosecution of science with a "sense of citizenship" almost aggressive in its energy. He had often to differ from his colleagues in questions of academical discipline and once in a crisis of the kind he had an altercation with Professor Tamassia so "vivacious" that by order of the Procuratore del Rè he was put under arrest. The students, who idolised him, broke out into open rioting and for three days they maintained a "barring out," surrounded by troops and tolling the great bell (*campanone*) renowned in Venetian history. When the besiegers and besieged came to terms none of the university authorities recalled the excited youth to their studies with more effect than Brunetti, interesting them in the latest accessions to science, particularly in the recent discovery of the bacillus choleræ in which he made independent and valuable researches. Among the many distinctions he held was that of honorary professor of the Imperial University of Charkow; while the Committee of the Paris Exhibition of 1867 bestowed on him its "grand medal of scientific merit," and a few years later the Universal Exhibition of Vienna, also through its committee, honoured him with its medal awarded for contributions to biological science. One of his specialties was that of embalming the dead, a *métier* almost exclusively Italian. From among numerous competitors he was chosen to embalm the body of King Victor Emanuel and but for adverse circumstances would have performed the same service in the case of Pius IX. The Paduan University for 48 hours after his death was draped in mourning and on Dec. 9th he was followed to the grave by all the notabilities of the city and province, the *oraison funèbre* being delivered with his accustomed felicity and effect by Dr. Achille De Giovanni, the Rector Magnificus.—Another loss sustained by Italian medicine is that of Dr. Giovanni Zoia, Professor of Anatomy in the Lombard University of Pavia. A native of Mantua, he distinguished himself, side by side with the patriot and statesman Benedetto Cairoli, in his country's fight for independence. This effected he threw himself with equal ardour into biological study and rose to be one of the best anatomists and teachers of anatomy in the Italian kingdom. Three years ago he lost two sons by Alpine misadventure and the bereavement so preyed upon him that he was never the same man again. A long malady supervened to which he succumbed on Dec. 16th, regretted by all the Lombard school and, indeed, by the whole civic population in whose welfare he took a quite philanthropic interest.—The last and not the least eminent of the trio is Dr. Giuseppe Pinto, who died on Dec. 18th in the Hospital of San Giacomo, in the Corso, in his fifty-seventh year. He was a Roman of the masculine, almost severe, type, very accomplished in his profession and devoted to its history, in which he published a well-written volume by way of supplement to the master-work of Puccinotti. He held the post of *privat-docent* in that subject in the University of Bologna and afterwards he filled the chair of hygiene in the School of Agriculture in Rome. In this capacity he did excellent work towards the "bonificamento" of the Campagna, the reclamation of marsh lands, and the re-afforesting of upland tracts denuded by reckless tree-felling. Himself also a patriot who joined in the movement by which Rome became the capital of United Italy, he was an active and enlightened provincial councillor, ever foremost in mitigating the lot of the agricultural poor. His malady was, like that of Professor Zoia, a lingering one—cancer of the throat, for the treatment of which he had placed himself under the care of the clinical staff of the San Giacomo Hospital.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Military Governor of Cuba a Sanitarian.

THE appointment of General Leonard Wood as Military Governor of Cuba is an event of the greatest importance to the future health and prosperity of the people of that island. General Wood is a graduate of the Harvard Medical School, and was in the active practice of his profession at the time of the outbreak of the war with Spain. At the close of the war he was made Military Governor of the Province of Santiago, and at once organised and put in operation sanitary measures designed to exterminate the pestilential diseases which had rendered that city almost uninhabitable. Chief among the diseases which annually scourged the city of Santiago was yellow fever, and though the season was well advanced when Dr. Wood assumed control so radical were the measures of sanitary cleansing which he rigorously enforced that the appearance of the fever was much delayed and when it did appear the local authorities had it under complete control. Though General Wood now enters upon a far wider field of service the duties are practically the same as those which occupied his thought in the Province of Santiago, viz., the promotion of the public peace and the public health. It is believed that he will inaugurate in Havana and the towns throughout the islands the same rigorous measures that have proved so efficient in Santiago. The result cannot be doubtful. Yellow fever, small-pox, and other kindred diseases which annually decimated the population of Cuba and were a constant menace to the health of the seaport cities of the United States, will be exterminated in the islands.

The Army Ration.

Dr. Charles Smart, Deputy-Surgeon-General and an expert chemist, makes the following statement in regard to the army ration:—"The United States ration is the most liberal ration in the world; it is the best ration for the far north-west of this continent, whence come the sub-zero cold waves to sweep over the country from the upper strata of the atmosphere, and it is the best for the tropics when intelligently utilised. It is the product of the experience of several generations of army officers, and it is the part of wisdom to be slow in urging alterations at the suggestion of people who know that an excess of fatty food is not suitable for a dietary in the tropics and who have just discovered that there are 12 ounces of bacon in the soldier's ration. Under the present law and regulations as to the ration the soldier can have any variation of his diet,

within certain money-value limits, which his officers consider necessary for his well-being. His ration is fixed by law and it is a most liberal one, but his dietary depends upon the intelligent supervision of his company officers and the ability of his company cooks. If a change in the dietary is advisable it lies with the company commanders to carry it into effect. The elasticity of the ration is wonderful. It is so elastic that the soldier may verily eat his candles if he does not require them for any other purpose. He may leave the candles in the hands of the subsistence department and if their money value will pay for a can of peaches or a pound of rice or for so much of any other of a long list of articles kept for sale by the subsistence officers, he can eat his candles' component in the form of peaches or rice or any other of the purchasable things. So with the bacon. He is no more required to eat that because it is a part of the ration than he is asked to eat the candles, but he may transform it into some other kind of food which he likes better or which is better for him under the climatic conditions which affect him at the time."

Mortality from Diphtheria in New York before and after the Introduction of the Antitoxin Treatment.

The following statistics of the mortality from diphtheria before and after the introduction of the antitoxin method of treatment have been kindly furnished to your correspondent to Dr. John S. Billings, jun., Assistant Director of the Bacteriological Laboratory of the Department of Health. The tables show the number of cases, deaths, and mortality per cent. of diphtheria in New York City (boroughs of Manhattan and the Bronx) from 1891 to Oct. 1st, 1899.

Before the Introduction of Antitoxin.

Period.	Cases.	Deaths.	Mortality per cent.
1891...	5364	1970	36·7
1892...	5184	2196	40 6
1893	7021	2558	36·4
1894...	9641	2870	29·7
After the Introduction of Antitoxin.			
1895...	10,353	1976	19·1
1896...	11.399	1763	15 4
1897...	10,896	1590	14·6
1898...	7593	923	12·2
Jan. 1st, 1898, to Oct. 1st, 1898	4778	695	14·5
Jan. 1st, 1899, to Oct. 1st, 1899	5100	782	15·3

The following table shows the number of cases of diphtheria in New York City (boroughs of Manhattan and the Bronx) in which antitoxin was administered free of charge by this department and others in 1898 and 1899, with the number of deaths, mortality, and also the corrected mortality after deducting the cases already moribund when antitoxin was administered.

Period.	Cases.	Deaths.	Mortality per cent.	Moribund deducted.	There remain. C.	There remain. D.	Mortality per cent.
1898.	1494	206	13·7	81	1413	125	8 8
1899 (first nine months only).	1358	170	12 5	61	1297	109	8·4

Dr. Billings adds:—"During the summer of 1899 the department has been testing the so-called globulin diphtheria antitoxin. It was found by the chemist of the department that when antitoxic serum was treated with magnesium sulphate and heated the antitoxic substances were precipitated along with the globulin. In this way 90 per cent. of the antitoxic substances may be extracted from the serum. By replacing the magnesium sulphate with sodium sulphate the globulins and antitoxins are again rendered soluble. In this way very concentrated solutions of antitoxin may be obtained, and the department is now testing this globulin in the Willard Parker Hospital for Contagious Diseases, in order to determine whether its use is followed by rashes and the other occasional sequelæ of ordinary antitoxic serum.

Dec. 18th, 1899.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Health of Sydney.

THE report of Mr. T. H. Kendall, medical adviser to the Metropolitan Water and Sewerage Board, Sydney, for the quarter ending Sept. 30th, 1899, has just been presented to the board. The population of Sydney has materially increased since the corresponding quarter of 1898, and shows a greater increase than for any similar period during the previous four years. The increase is chiefly due to a decrease in the death-rate, the total number of deaths having been 1190 as against 1875 for the corresponding period of 1898. The mortality from diarrhœal diseases shows a very marked decrease, attributed by Mr. Kendall to the extension of the sewerage system. Diphtheria and tuberculosis have also claimed fewer victims, a result which is attributed to the drying of the soil brought about by the laying down of the sewers. To keep up the improvement Mr. Kendall insists on the necessity of destroying all garbage by fire in destructors. Typhoid fever has increased in prevalence, 108 cases being reported, as against 68 for the same quarter of 1898, and 34 for that of 1897. Many cases were traced to the milk-supply, and Mr. Kendall points out that Pasteurisation of milk is useless against infection in the milkshop and during delivery. Attention is called to the dangers lurking in the concoction known as "ice-cream," in which more and worse bacterial bodies are found than in concentrated sewage. This statement was brought under the notice of the Legislature by Dr. Ross and the Health Department replied that attention had been given to the matter, that the comparison with concentrated sewage could not be rightly made, and that the execution of the Adulteration Clauses of the Health Act was rigid so far as the Board of Health took part in it, but that the local authorities rarely took proceedings.

The Standard of Milk.

Some time ago, as stated in these columns at the time,[1] the New South Wales Board of Health fixed a milk standard. Recently the inspector of nuisances for Marrickville prosecuted a dairyman for selling milk which did not contain the quantity of butter fat required by this standard. The dairyman was fined by the stipendiary magistrate, but appealed to the Full Court, who reversed the decision on the ground that the milk was received by the inspector in absolutely the same state as that in which it left the cow and was not adulterated either by addition of water or the subtraction of cream, and as the dairyman had done all that could be reasonably required of him he was not liable to a penalty. Further, the purchaser had simply asked for milk, not for milk of the standard prescribed by the Board of Health, and he received milk, and the Health Act did not make the supplying of milk not up to the standard fixed by the Board an offence. In consequence of this decision by the Full Court Dr. Ashburton Thompson, President of the Board of Health, states that if the public wish to have a standard for milk the Legislature will have to amend the Health Act. The Board when fixing the standard was in some doubt whether it would be binding in a court of law.

Small-pox on s s. Nineveh.

When the s s. *Nineveh*, from London *viâ* the Cape of Good Hope, arrived at Fort Phillip Heads and was boarded by the pilot he was assured that she had a "clean" bill of health. The port health officer, Dr. Howard, on investigation differed from this opinion and diagnosed a case of small-pox in a steerage passenger. The ship's surgeon—whose name by a curious coincidence is Jenner—maintained that the disease was not small-pox. Dr. McLean, the other port health officer, supported the view of his colleague, and the vessel was quarantined. The vessel was allowed to discharge her Melbourne cargo into lighters and the passengers were put into quarantine, the mails were fumigated, and the vessel proceeded to Sydney. All the passengers at the quarantine station were vaccinated and two more undoubted cases of small-pox subsequently developed.

Outbreak of Beri-beri on Board Ship.

When Dr. McLean, port health officer for Melbourne, boarded the ship *Stirling* he found the captain, steward, and two seamen suffering from beri-beri, while the second mate

[1] THE LANCET, Feb. 11th, 1899, p. 413.

had died from apparently the same disease during the voyage. The vessel had an unusually protracted voyage from Archangel and the stock of vegetables gave out. The crew were served with rice and preserved potatoes. The rice was found on examination by Dr. McLean to contain a fungoid growth.

Appointments.

Dr. George Rothwell Wilson Adam has been appointed lecturer on obstetrics and diseases of women at the University of Melbourne in place of Dr. Balls-Headley, who has resigned. The university lecturer is *ex officio* a member of the honorary staff of the Women's Hospital, Melbourne. Dr. Adam is already on the staff of this institution by election, and it is doubtful whether a vacancy will now occur for the elective post.—Several changes have been made in the staff of St. Vincent's Hospital, Melbourne. Mr. F. W. W. Morton and Dr. R. A. Stirling have retired from the position of physician and surgeon respectively, and have been appointed to the consulting staff. Mr. W. F. Moore has been appointed surgeon in place of Dr. Stirling. Dr. Murray Morton and Mr. F. A. Newman have been appointed surgeons to out-patients, and Dr. J. F. Wilkinson and Dr. F. O'Sullivan, physicians to out-patients. The rest of the staff were re-appointed to their respective positions.

Dec. 1st, 1899.

Obituary.

ALEXANDER GRANT, F.R.C.S. EDIN.,

SURGEON-MAJOR, BENGAL ARMY (RETIRED); HONORARY SURGEON TO THE QUEEN.

MR. ALEXANDER GRANT, who has recently died in London at an advanced age, entered the Bengal Medical Service in 1840 and retired as surgeon-major soon after returning to England in 1861. His career was a distinguished one. He served with the 55th Foot during the Chinese war of 1841-42, and was officially thanked by his superior officer when the regiment returned to England. Having been appointed civil surgeon of Bhagulpore, he was ordered to join the army of the Sutlej in the first Sikh war. He subsequently became civil surgeon of Chapprah, and in 1849 was appointed surgeon to the Governor-General, which office he held till Lord Dalhousie's return to England in 1856. He had been appointed Presidency surgeon and surgeon to the Presidency General Hospital, Calcutta, a much-coveted appointment, and on his return from England, whither he had accompanied Lord Dalhousie, he held the important office of apothecary-general, and as such rendered valuable services in providing medical stores for the army in the field during the period of the Mutiny, for which he received the thanks of the Government of India and the Secretary of State. He had held the important office of President of the Medical Faculty in the University of Calcutta. Failing health compelled Mr. Grant to return to England in 1861, but he continued to do useful work and to take great interest in the service of which he had been so brilliant an ornament and to which he rendered such valuable aid by his influence with the great Governor-General, whose memorable despatch respecting the Indian Medical Service was based on the information furnished by Mr. Grant. Mr. Grant was much respected, trusted, and beloved by all who knew his sterling uprightness, unselfishness, and modesty, which were not less appreciated than his great abilities and unswerving devotion to duty. His memory will be cherished not only by the Indian Medical Service but by all who knew him in India, England, and elsewhere.

WILLIAM NEALOR THURSFIELD, M.D. EDIN., M.R.C.S. ENG., D.P.H. CAMB.

BY the death of Dr. Thursfield the department of public health has sustained a loss which will be deplored not less by his colleagues than by the members of the numerous sanitary authorities to whom he has rendered most faithful and ungrudging service during the past quarter of a century. William Nealor Thursfield was born in the year 1840 in Shropshire, the county with which his name and work will always be most closely associated. After leaving Marlborough College he entered at King's College where he came under the influence of Sir William Fergusson, and subsequently he joined the University of Edinburgh where he graduated M.D. in 1862, after having obtained his M.R.C.S. Eng. in the previous year. In 1877 he received the recently created D.P.H. Camb. During the first year after his graduation he held a commission at Netley which he resigned owing to the serious illness of his father, upon whose death he took medical charge of an emigrant ship to New Zealand. While in this colony he gathered together a most valuable collection of arms and implements.

Dr. Thursfield's first public health appointment was in 1870 when he was elected medical officer of health for the town of Wellington, in Shropshire, where he also engaged in general practice. In 1873 he was appointed medical officer of health to a large combination of urban and rural districts which were subsequently added to in number until he became responsible for the public health administration in some part or other of no fewer than seven contiguous counties. In 1897 he gave up these district appointments and was elected medical officer of health to the county of Salop. After the arduous labour entailed by his large combination of districts he looked forward to many years of good work, but anticipated in connexion with it less stress and anxiety. It is pathetic, therefore, to record that within a few months of his election to the county appointment he developed ataxic symptoms, so that until the time of his death on Dec. 19th last he could attend to his duties with increasing intermittence. The influence of every medical officer of health to a large district must of necessity extend far beyond his own immediate area of administration, but in the case of Dr. Thursfield that influence was extended in a manner that was unique, for the mere physical conformation of his district necessitated the constant employment of a qualified assistant. The experience gained by those gentlemen who were fortunate enough to be associated with him has always stood them in good stead, and they are now to be found carrying on public health work in various parts of Great Britain, as far north as the county of Lanark and down in the south in the county of Glamorgan. Dr. Thursfield was at one time a president of the Incorporated Society of Medical Officers of Health and of the Birmingham and Midland Branch of the society. In addition to his most valuable series of reports he contributed many papers upon subjects relating to his own special branch of practice.

JAMES HOWISON, L.R.C.P., L.R.C.S., L.M. EDIN.

A LARGE circle of medical friends and patients in the north will regret to hear of the death, in his seventy-seventh year, of Mr. James Howison of 33, Abbey-road, London, N.W. Mr. Howison was descended from a long line of medical men on the maternal side, representatives of three generations having practised in the city of Durham at the same time. He had also three uncles in the profession. He was for many years connected with the old Edinburgh Infirmary, where he held the positions of house physician, house surgeon, prosector of anatomy, instructor in the treatment of fractures and of bandaging, apothecary, and cupper. While at the infirmary he designed an inhaler which is known by his name and also a form of splint for club-foot. On leaving Edinburgh he held two appointments as physician in private families, and then he went to Darlington, where he was soon appointed honorary surgeon to the hospital—a position which he held for nearly 20 years. During the time when Darlington was the centre of the iron industry he was appointed surgeon to all the works there.

The following is a quotation from an illuminated address which was presented to him (with a purse of gold) on his leaving Darlington: "We beg to assure you, Sir, that we part from you with the utmost regret. You have endeared yourself to numbers of us and our families by your kindness of heart, courteous, and gentlemanly bearing, your remarkable frankness and candour as a medical man, and, moreover, the solicitude you have ever evinced for the recovery and welfare of your patients. We have the highest appreciation of your skill, not only as a surgeon, but in the wider field open to the physician in the region of medical science. With a naturally acute and appreciative mind you have ever been ready to seek for and adopt the most advanced knowledge in connexion with the profession of which you are so conspicuous an ornament." Mr. Howison towards the close of his life had lost his sight, being quite blind in one eye and

partially blind in the other. Blindness was the cause of his death by a sad accident. On Saturday afternoon, Dec. 23rd, as a train going to Baker-street was entering West Hampstead Station during a dense fog the engine-driver felt the engine going over something. Mr. Howison was then found lying flat on his back between the rails and the side of the platform, having evidently stepped over the side in the dark. He was much injured and was conveyed to University College Hospital, Gower-street, but he died on the way thither.

DAVID CULLEN, M.D., L.R.C.S. EDIN.,
DEPUTY SURGEON-GENERAL, A.M.D.

ON Jan. 4th Deputy Surgeon-General David Cullen, A.M.D., passed away peacefully at his residence, Halsey House, Cheltenham, in the sixth-seventh year of his age, after seven weeks' illness. Deceased some five years ago was the subject of prostatic disease, but later he developed symptoms of abdominal malignant disease, which a few months ago became complicated by ascites. No doubt through a desire to avoid giving anxiety to his family and relatives he maintained a marked reticence respecting his condition and avoided all reference to his malady. Till seven weeks ago Dr. Cullen maintained his general habits of life, enjoying the society of his family and friends, walking out daily, always cheerful and uncomplaining; but then, finding that he needed help, he sent for his friends Dr. John Bramwell and Mr. Cripps Lawrence, who attended him till he was released. The day before his death, the ascites having increased, threatened to add to his suffering, and relief was obtained by paracentesis. Dr. David Cullen graduated M.D. Edin. and L.R.C.S. Edin. in 1854 and served in the Army Medical Department from 1854 to 1869; during that period he was an assistant surgeon on the staff of the 6th Light Dragoons, the 3rd Battalion Rifle Brigade, and the 17th Lancers. He served in the Crimea from 1854 to 1856 and in the Indian Mutiny from 1857 to 1859. Later he was surgeon-major in the 71st Highland Light Infantry and was registrar to the Royal Victoria Hospital, Netley, from 1875 to 1880, after which he retired on a pension. Dr. Cullen was awarded medals for his services in the Crimea, in Turkey, and in the Indian Mutiny, and clasps for Sebastopol and Lucknow. For the last 18 years Dr. Cullen has resided in Cheltenham.

JOHN GORHAM, M.R.C.S. ENG., L.S.A.

ON Dec. 13th, 1899, there passed away John Gorham, one of the oldest and best known practitioners of Tonbridge. He was educated at Tonbridge School and studied medicine at Guy's Hospital, becoming L.S.A. in 1835 and M.R.C.S. Eng. in 1839. Returning to Tonbridge he entered into partnership with Dr. West, who was a well-known surgeon of the day. Mr. Gorham paid special attention to the physical side of science and wrote much and brilliantly upon light and crystallography. Among his works were "Unfrequented Paths in Optics: Part 1, Light from a Pinhole; Part 2, Light from a Fissure"; "A System for the Construction of Crystal Models on the Type of an Ordinary Plait"; "The Rotation of Coloured Discs," *Quarterly Journal of the Microscopical Society*, 1859; "Mode of Calculating Hexagonal Facets in Cornea of the Eye in Insects"; "The Diascope, a New Optical Instrument"; "Rudiments of Colour by Rotation," *Transactions of the Royal Microscopical Society;* "The Stereograph, for Delineating Solids in Space"; "Venation in Leaves of Umbelliferæ"; "On the Composite Structure of Simple Leaves"; "Tooth Extraction, a Manual on the Proper Mode of Extracting Teeth"; "The Tubular Balance"; "Intussusception in Infants"; "On the Blending of Colours by the Sole Agency of the Sensorium," *Brain*, 1882; "The Pupil Photometer"; and papers upon "Ovarian Dropsy" and "Respiration and Pulse in the Infant" which appeared in our columns. He was in his eighty-fifth year.

FREDERICK WILLIAMS LEWIS, M.R.C.S. ENG.

MR. FREDERICK WILLIAMS LEWIS died, after a few hours' illness, at his residence, Violet Cottage, Llandovery, towards the end of last year. He received his medical education at the Middlesex Hospital. After qualifying M.R.C.S. Eng. in 1873, he became house surgeon to that institution. He afterwards came to Llandovery, where he became partner to Dr. Thomas, to whose practice he succeeded. He was at once in the full swing of practice. He became medical officer for the No. 1 district of Llandovery Union, medical officer of health for the Llandovery Urban and Rural District, and surgeon to the Great Western, Vale of Towy, and London and North-Western railway companies. He was a conspicuously able accoucheur and a courageous and dexterous surgeon, and results of operations performed by Mr. Lewis remain as striking examples of neat and successful surgery. By his unceasing kindness, sympathy, and liberality, Mr. Lewis had endeared himself to rich and poor alike. The poor especially have lost in him a warm-hearted and most generous helper and friend. The funeral procession was one of the largest ever witnessed in Wales.

GEORGE CHEESMAN, L.R.C.P. EDIN., M.R.C.S. ENG.

WE regret to announce that Mr. G. Cheesman, who had been the medical officer for the Southampton Incorporation for many years, and who was formerly a very well-known practitioner in the town, died at his residence, Grendahr, Hillside-avenue, Bitterne-park, on Jan. 2nd, at an advanced age. He represented the old All Saints Ward in the council for a number of years prior to the redistribution of seats.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. J. Paetsch, professor in the Berlin Dental Institute.—Dr. Tirant, who formerly held an important official post in French Cochin China, where he made important zoological observations.—Dr. Johann Mitvalsky, an ophthalmologist of considerable reputation on the teaching staff of the Bohemian University of Prague. He was 38 years of age.

Medical News.

UNIVERSITY OF LONDON.—At the B.S. examination for honours the following candidates were successful:—

Surgery.—First Class: Thomas Rupert H. Bucknall, M.D., London Hospital; Mabel G. Stevenson (gold medal), Royal Free Hospital; Wilfred B. L. Trotter, M.D. (scholarship and gold medal), University College; and Jane Holland Turnbull, Royal Free Hospital. Second Class: Philip Turner, B.Sc., Guy's Hospital.

N.B.—The foregoing list, published for the convenience of candidates, is provisional only, and is not final until the reports of the examiners shall have been confirmed by the Senate.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination held in January the following candidates passed in the subjects indicated:—

PART I.

Biology.—B. F. Board and C. Kellgren, Royal Free Hospital; R. V. Khedkar, Bombay; D. Mann, Royal Free Hospital; A. Rogers, Cardiff; and J. S. Wilkes, Birmingham.
Chemistry.—C. T. Price, St. Bartholomew's Hospital, and G. W. N. Stevens, Charing-cross Hospital.
Materia Medica and Pharmacy.—K. C. Edwards, Cambridge and Glasgow; A. W. Ellis, Edinburgh; F. A. Segreda, Guy's Hospital; P. G. Sheppard, Cambridge and Liverpool; A. D. Sibree and D. A. Stepney, Royal Free Hospital; and J. H. Williams, London Hospital.

PART II.

Anatomy.—A. T. Barnard, Royal Free Hospital; T. J. M. Clapperton, King's College Hospital; P. S. Cooke, Charing-cross Hospital; A. W. Ellis, Edinburgh; H. R. Grellet, Guy's Hospital; F. H. Hand, St. Mary's Hospital; E. M. Handley, Royal Free Hospital; J. A. Kilpatrick, King's College Hospital; A. R. McEnnery, Bristol; O. Millauro, Charing-cross Hospital; T. Scatchard, Leeds; R. H. Terry, Guy's Hospital; A. Turner, Charing-cross Hospital; F. J. Turner, Guy's Hospital; and J. A. W. Webster, St. Mary's Hospital.
Physiology.—A. T, Barnard, Royal Free Hospital; F. C. Bourns, Westminster Hospital; E. M. de Wilton, St. Mary's Hospital; C. D. E. Forbes, St. George's Hospital; E. M. Handley, Royal Free Hospital; F. H. Maberly, Birmingham; O. Millauro, Charing-cross Hospital; H. Morrison and T. Scatchard, Leeds; R. H. Terry, Guy's Hospital; A. Turner, Charing-cross Hospital; J. A. W. Webster, St. Mary's Hospital; and C. M. Woods, Charing-cross Hospital.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Karl Schweigger has decided to resign the chair of Ophthalmology at the end of the winter session. Dr. Uhthoff of Breslau has been nominated as his successor.—

Dr. Wilhelm Kolle, who has been working in Kimberley in connexion with Koch's investigations on South African cattle plague and has recently resumed his old post as assistant medical officer of the Berlin Institute for Infectious Diseases, has been appointed Professor.—*Budapest:* Dr. A. Szekely has been recognised as *privat-docent* of Infectious Diseases.—*Gratz:* The chair of Ophthalmology, vacant by the death of Dr. Borysiekiewicz, has been offered to, and declined by, Dr. W. Czermak of Prague.—*Halle:* Dr. Kast of Breslau is expected to follow Dr. T. Weber, who is retiring from the chair of Special Pathology and Therapeutics.—*Heidelberg:* Dr. Hofmokl, Extraordinary Professor of Surgery, is retiring on account of his health.—*Leipsic:* Dr. Felix Marchand of Marburg has been offered the chair of Pathological Anatomy, vacant by the death of Dr. Birch-Hirschfeld.—*Prague (Bohemian University):* Dr. Rudolf Kimla, *privat-docent*, has been granted an Extraordinary Professorship.—*Leyden:* Dr. P. Kan has been recognised as *privat-docent* of Otology and Rhinology.—*New York (Polyclinic and Hospital):* Dr. M. Manges has been appointed Professor of Medicine.

FEMALE STUDENTS ADMITTED AT HEIDELBERG.—The medical faculty of the University of Heidelberg has decided to admit female students on the same terms as "regular" male students—that is to say, they must produce a "maturity" certificate from a German gymnasium. "Occasional" female students will not be admitted.

CONVALESCENT HOME FOR WOUNDED SOLDIERS AT TORQUAY.—An influential committee has been appointed to promote a fund for opening a convalescent home at Torquay for wounded soldiers from South Africa. A large villa, which commands some of the finest coast scenery on the shores of Devon, has been placed at the disposal of the committee.

LUNACY IN SOMERSET.—At the meeting of the Somerset County Council held on Jan. 2nd it was reported that there were 847 patients in the Wells Asylum and 462 at Cotford, making a total of 1309 (782 females and 527 males). It was stated that the expenditure at the latter asylum now amounted to £172,170, although originally it was estimated that the cost would be £100,000.

PRESENTATION TO A MEDICAL MAN.—At Newick, Lewes, on Dec. 30th, a small party of friends met at the rectory to present Mr. Richard Gravely, M.R.C.S., with a jubilee testimonial to mark the completion of his 50 years' residence in the village. The rector, on behalf of the subscribers, made the presentation. The testimonial consisted of a solid silver antique inkstand, a pair of silver candlesticks, a case containing a silver pen, pencil, and paper-knife, a cheque, and an illuminated address which contained the names of more than 90 subscribers. On the inkstand is engraved: "Presented to Richard Gravely, Esq., resident in Newick 50 years—1849-1899—by his many friends," and the address itself states: "This testimonial is presented to Richard Gravely, Esq., together with a gift of silver, subscribed for by those whose names appear below, in token of their appreciation of the constant interest shown by him in the welfare of the inhabitants of Newick and the neighbourhood during his 50 years' residence among them."

MEDICAL SLANDER CASE.—At Cardiff on Jan. 5th the under sheriff (Mr. Lawrence Williams) awarded Dr. T. H. Morris £35 damages against Mr. R. W. Willis, an itinerant patent medicine vendor. Evidence showed that on Sept. 20th a young man fractured both his legs in falling from a railway-carriage. Dr. Morris was sent for and, finding amputation was required, after having rendered assistance, took the patient to the Cardiff Infirmary, where he died within two hours. The jury at the inquest found that no fault was attributable to anyone. The defendant wished to accompany Dr. Morris to the infirmary with the patient, but as there was plenty of assistance this was refused. Willis then went to an hotel at Tylorstown and there said, in the presence of Mr. T. Parry and several others, that "Dr. Morris did not know his work and made no attempt to save the young man and if he were the young man's father he would have taken him by the neck and pitched him under the train." Speaking from a van later to about 200 people he made a similar statement, adding that "if Dr. Morris had done what he ought the young man's life would have been saved."

BRIXHAM (DEVON) HOSPITAL.—At the eighth annual meeting of this institution held recently it was stated that for the first time in its history there was a favourable balance. 83 in-patients and 992 out-patients had been treated. The receipts amounted to £535 and the expenditure to £516.

SUPERANNUATION ALLOWANCES.—Dr. John Shoolbraid has been awarded a pension of £50 per annum by the Aldershot District Council on his retirement as medical officer of health of Aldershot.—Mr. Daniel B. Balding, F.R.C.S. Eng., has been granted a superannuation allowance of £34 per annum by the Royston (Herts) Board of Guardians on his retiring from the post of medical officer to the workhouse.

MEDICAL MAGISTRATES.—The following gentlemen have been appointed justices of the peace for New South Wales—namely: Francis Alexander Bennet, M.D. Aberd., of Sydney; Thomas Benedict Clune, L.R.C.S. Irel., of Petersham; Cambridge Cary Cocks, M.D., of Wentworth; James Graham, M.D. Edin., of Sydney; Henry Louis Harris, M.B., of Tamworth; Alfred Wynter Hawthorne, M.D. R.U.I., of Carcoar; Evan Lewis Hickey, M.D. Durh., of Nyngau; John William Kennedy, F.R.C.S. Irel. of Hay; Michael John Lyden, M.D., of Sydney; George Archibald Innes Mackay, L.R.C.P. Edin., of Maclean; John Michael M'Donagh, M.D. Brux., of Sydney; Sydney Sargent Merrifield, M.R.C.S. Eng., of Bombala; George Edward Miles, L.R.C.P. Lond., M.R.C.S. Eng., of Rydalmere; Alfred Edward Perkins, M.B. Syd., of Marrickville; and Charles Daniel Hartley Rygate, M.R.C.S. Eng., of Wellington.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ANDREWS, C. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer for the Sixth Sanitary District of the Norwich Union.

BAILES, NORMAN CHRISTIAN, M.B., B.S. Durh., has been appointed Resident Surgeon to the General Dispensary, Birmingham.

BLACK, JOHN, L.D.S. Eng., has been appointed Dental House Surgeon to Guy's Hospital.

BLANDFORD, L. J., M.B., B.S. Durh., has been appointed House Surgeon to the Royal Infirmary, Newcastle-on-Tyne.

CAMPKIN, HUGH T., L.D.S. Eng., has been appointed Dental House Surgeon to Guy's Hospital.

CORRIE, A. T., L.R.C.P. Edin., M.R.C.S., Fleet Surgeon, has been appointed in medical charge of the Dockyard and Royal Naval Barracks at Sheerness.

CROOK, A., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer for the Fourth Sanitary District of the Norwich Union and the Boys' Home.

DARRELL, H. W., M.D. Toronto, L.R.C.P. Lond., has been re-appointed Medical Officer for the Third Sanitary District of the Norwich Union.

DOWLING, A., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Union Medical Officer for Haydock.

DYER, S. REGINARD, M.D. Brux., M.R.C.S., L.R.C.P. Lond., D.P.H. Eng., Conjoint Board, Barrister-at-Law, has been appointed Medical Officer H.M. Prison, Stafford.

FIELD, A. T., M.R.C.S., has been appointed Medical Officer for the Wymondham Sanitary District of the Melton Mowbray Union, vice R. Moreton, resigned.

GOFFE, E. G. L., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Assistant Medical Officer at the Lewisham Union Infirmary, vice E. R. Badcock.

GOFTON, EDWARD, M.B., B.S. Durh., has been appointed Assistant House Surgeon to the Royal Infirmary, Newcastle-on-Tyne.

HARDWICKE, G., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Resident Medical Officer by the Leeds City Council.

JAMES, M. B., M.B., Ch.B. Vict., has been appointed Assistant Medical Officer for the Workhouse and Infirmary of the Parish of St. Mary, Islington, vice M. G. Dyson, resigned.

MCCONNELL, JAS., M.B., B.S. Durh., has been appointed House Surgeon to the Royal Infirmary, Newcastle-on-Tyne.

MACGOWAN, J. S., M.D. Lond., M.R.C.S., has been appointed Medical Officer for the Fifth Sanitary District of the Township of Oldham, Oldham Union, vice J. H. Fletcher, resigned.

MCMURRY, J., M.D., R.U.I. (civil surgeon), has been appointed to a vacancy on the medical staff of the Western District.

MAURICE, ALBERT, L.D.S. Edin., has been appointed Dental Surgeon to the Belgrave Hospital for Children, Gloucester-street, London.

MEARNS, JAMES, A., M.B., C.M. Aberd. (civil surgeon), has been appointed to a vacancy on the medical staff of the Western District.

MORRISON, R., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Duffield Sanitary District of the Belper Union, vice F. D. Holmes, deceased.

MUIRHEAD, JAS., M.B., B.S. Durh., has been appointed Junior House Physician to the Royal Infirmary, Newcastle-on-Tyne.

NORTON, J. J., L.R.C.S., L.K.Q.C.P. Irel., has been appointed Medical Officer for the Alrewas Sanitary District of the Lichfield Union, vice J. J. Spears.

PARRY, T. L. (civil surgeon), has been appointed to a vacancy on the medical staff of the Western District.

PEARCE, FRANK J., L.D.S. Eng., has been appointed Dental House Surgeon to Guy's Hospital.

ROSSITER, C. B., F.R.C.S. Edin., has been appointed Clinical Assistant to the St. John's Hospital for Diseases of the Skin, Leicester-square, London.

ROWLAND, FRANK, L.R.C.P., L.R.C.S. Edin., has been appointed Resident Surgeon to the Birmingham General Dispensary.

SCOTT, NORMAN E. H., M.B., Ch.B. Glasg., has been appointed House Physician to the North-Eastern Hospital for Children, Hackney-road, Shoreditch, N.E.

SIEGER, A. A. (civil surgeon), has been appointed to a vacancy on the medical staff of the Western District.

SIMPSON, WM., M.B., B.S. Durh., has been appointed Senior House Physician to the Royal Infirmary, Newcastle-on-Tyne.

SPOWART, W. R., M.D. Dub., L.R.C.P., L.R.C.S. Irel., has been re-appointed Medical Officer for the Eighth Sanitary District of the Norwich Union.

STACY, J. H., L.R.C.P., L.R.C.S. Edin., has been re-appointed a District Medical Officer for the Norwich Union.

YOUNG, A. G., M.B., C.M. Glasg., has been appointed Medical Officer for the Castle Bytham Sanitary District of the Bourne Union, vice J. B. Richardson, resigned.

VALENTINE, WM., L.R.C.P., L.R.C.S. Edin., has been appointed Union Medical Officer for Newton.

WATSON, H., M.D. Aberd., C.M., has been re-appointed Medical Officer for the Fifth Sanitary District of the Norwich Union.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

ABERYSTWITH INFIRMARY.—House Surgeon. Must also act as Secretary. Knowledge of Welsh essential. Salary £150, with the usual residential allowances (stimulants excepted).

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Birmingham.—Assistant House Surgeon. Salary £50 per annum, with apartments and board.

BOLTON INFIRMARY AND DISPENSARY.—Junior House Surgeon for twelve months. Salary £80 per annum, with apartments, board, and attendance.

BRECON INFIRMARY, South Wales.—Resident House Surgeon, unmarried. Salary £80 per annum, with furnished apartments, board (all found except beer), attendance, fire, and gas.

CARDIFF INFIRMARY.—Assistant House Surgeon and Assistant House Physician for six months. Salary at the rate of £50 per annum, with board, washing, and apartments.

CHESTER GENERAL INFIRMARY.—Visiting Surgeon for two years. Salary £80 per annum, with residence and maintenance in the house.

CITY OF LIVERPOOL.—Visiting Physician to the City Hospital North, Netherfield-road. Salary £130 per annum. Applications to the Town Clerk, Liverpool.

DERBYSHIRE ROYAL INFIRMARY, Derby.—Resident House Physician for 12 months. Salary £100 per annum, with apartments and board.—Also Resident Assistant House Surgeon for six months. Salary £30 for that period, with apartments, board, &c.

DONCASTER GENERAL INFIRMARY AND DISPENSARY.—Indoor Dispenser and Assistant to the House Surgeon. Honorarium £20 guineas per annum, with board, lodging, and washing.

DUNDEE COMBINATION POORHOUSES AND HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with board and furnished apartments. Apply to the Clerk of Council, Council-chambers, Dundee.

GLAMORGAN COUNTY ASYLUM, Bridgend.—Junior Assistant Medical Officer, unmarried. Salary £150, with board, apartments, washing, and attendance.

GLASGOW EYE INFIRMARY.—Resident Assistant House Surgeon. Salary £50, with apartments and board.

GROVE HALL ASYLUM, Bow, London.—Junior Assistant Medical Officer. Salary £120 a year, with board, apartments, washing, and attendance. Personal application to Medical Superintendent desirable.

HOSPITAL AND DISPENSARY, Newark-upon-Trent.—House Surgeon, unmarried. Salary £80 per annum, with board and lodging in the hospital.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, London.—Registrar and Pathologist. Honorarium 25 guineas per annum.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London.—Assistant Surgeon. Also two Assistant Physicians.

HOSPITAL FOR WOMEN, Soho-square (the London School of Gynæcology).—Clinical Assistantships.

LEEDS GENERAL INFIRMARY.—Resident Casualty Officer. Salary £100 a year, with board, lodging, and washing. Also House Physician for six months. Board, lodging, and washing provided.

LEICESTER INFIRMARY.—House Physician for twelve months. Salary £100 per annum, with board apartments, and washing.

LONDON LOCK HOSPITAL, Harrow-road, W.—House Surgeon to the Female Hospital. Salary £80 per annum, with board, lodging, and washing.

METROPOLITAN DISPENSARY, Cripplegate, E.C.—Resident Medical Officer. Salary £100 per annum, furnished residence, and an allowance for coal and gas. Apply to the Secretary, Cripplegate Institute, Golden-lane, London, E.C.

NEW HOSPITAL FOR WOMEN, 144, Euston-road, London.—Senior Assistants in the Out-patient Department, fully qualified (females), for two years.

NOTTINGHAM GENERAL HOSPITAL.—House Surgeon for two years. Salary £100, rising £10 a year to £120, with board, lodging, and washing.

NORTHAMPTON GENERAL INFIRMARY.—Assistant House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, attendance, and washing.

NORTH LONDON HOSPITAL FOR CONSUMPTION, Hampstead.—Assistant Resident Medical Officer for six months. Honorarium at the rate of £60 per annum. Apply to the Secretary, 41, Fitzroy-square, W.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon. Salary £140 per annum. Special arrangement as to board, &c.

PARISH OF ROUSAY AND EDILSHAY, Orkney.—Resident Medical Officer. Salary £51 per annum. Apply to the Inspector of Poor, Rousay, Orkney.

PLYMOUTH BOROUGH ASYLUM.—Assistant Medical Officer, unmarried. Salary £125 per annum, with furnished apartments in the Asylum, board, and washing free.

ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.—Assistant House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.

ROYAL SEA-BATHING HOSPITAL, Margate.—Assistant Resident Surgeon. Salary £52 per annum, with board and residence. Applications to the Secretary, Royal Sea-Bathing Hospital Offices, 30, Charing-cross, London, S.W.

ST. GEORGE'S HOSPITAL, London.—Curator of the Museum, and an Assistant Curator. Salary £100 a year for the Curator and £50 a year for the Assistant Curator.

ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, London.—Honorary Physician. Also House Surgeon for not less than six months. Salary £50 per annum, with board, lodging, and washing.

TORBAY HOSPITAL, Torquay.—House Surgeon. Salary £100 per annum and £5 for nurses' lectures. Board, lodging, washing, and attendance provided (wine, spirits, and beer excepted).

WALSALL AND DISTRICT HOSPITAL.—Resident House Surgeon. Salary £100 per annum, board, lodging, and washing.

WEST KENT GENERAL HOSPITAL, Maidstone.—House Surgeon, unmarried. Salary 100 guineas per annum, with board and residence, &c., rising 10 guineas a year to 120 guineas.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Acting Assistant Surgeon.

WEST RIDING ASYLUM, Wakefield.—Assistant Medical Officer to act as Locum Tenens for one month. Salary £3 3*s.* per week, with apartments and board.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY, Whitehaven.—House Surgeon. Salary £120 per year and £30 a year for dispensing, with furnished apartments and attendance.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—Assistant House Surgeon for six months. Honorarium at the rate of £50 per annum, and board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

ALDRIDGE.—On Jan. 2nd, at Rockstone House, Southampton, the wife of Norman E. Aldridge, M.B., of a daughter.

COSENS.—On Jan. 3rd, at Oxford-terrace, the wife of C. H. Cosens, M.R.C.S. L.R.C.P., of a daughter.

DOW.—On Jan. 4th, at High-street, Lewes, Sussex, the wife of William A. Dow, M.D., of a daughter.

WREFORD.—On Jan. 3rd, at Mount Edgcombe-gardens, Clapham-road, S.W., the wife of S. Wreford, M.R.C.S., of a daughter.

MARRIAGES.

HART—HAWKES.—On Jan. 8th, at the Congress Hall, Clapton, by Commissioner Pollard, Chancellor of the Salvation Army Exchequer, Arthur Herbert Hart, M.S., M.D., M.R.C.S., L.R.C.P., Medical Superintendent to the International Headquarters and of Bannockburn, Lordship-lane, Bruce-grove, to Kate, eldest daughter of Thomas Hawkes of Boscombe, Bournemouth.

PRALL—PINSENT.—On Nov. 1st, 1899, at St. Thomas's Church, Calcutta, by the Rev. C. Anstey, Cedric Barkley Prall, Captain, Indian Medical Service, youngest son of the late Richard Prall of Frindsbury, Kent, to Kathleen Blanche, younger daughter of William Swain Pinsent of Rose-hill, Newton Abbot, South Devon.

SEALY—POWELL.—On Jan. 4th, at St. Barnabas's, South Kennington, Francis Marmaduke Sealy, M.R.C.S., L.S.A., of Sutterton, Boston, to Harriett Catherine, daughter of the late James Turner Powell of Guildford-road, S.W.

WATSON—BARRETT.—On Jan. 3rd, at St. Luke's Chapel in Norwich Cathedral, Charles R. Watson, M.D. Brux., of Tunbridge Wells, to Grace Elspeth, daughter of Rev. Canon Barrett of Lincoln.

DEATHS.

CULLEN.—On Jan. 4th, at his residence, Halsey House, Cheltenham Deputy-Surgeon-General David Cullen, Army Medical Department, retired.

DUDLEY.—On Jan. 2nd, at Hova-villas, Hove, Sussex, John Gardner Dudley, M.A., M.D. Cantab., in his 72nd year.

ELDER.—On Jan. 6th, at 7, Leopold-place, Edinburgh, George Elder, M.D., F.R.C.P. Edin.

GRANT.—On Jan. 3rd, at 3, Connaught-square, Hyde Park, London, Alexander Grant, F.R.C.S., Surgeon-Major, late of the Bengal Service, and Honorary Surgeon to the Queen, aged 82

LONG.—On Jan. 2nd, at Crowborough, Sussex, Henry Plater Long, M.R.C.S., aged 60.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE CLERGYMAN AND THE MEDICAL MAN.

WE have frequently pointed out that it is the duty and privilege of the Church to look after people's bodies as well as after their souls. When, however, the clergyman steps out of his proper sphere and usurps the place which properly belongs to a medical man it is time to point out that he is exceeding his duties. We are led to these remarks by a paragraph which appears in the *Eastern Morning News* of Jan. 3rd, 1900, concerning certain villages in the Wolds of Yorkshire, which are some 10 miles from a medical man. As under these circumstances the visit involves a journey of some 20 miles, it is not surprising to find that one practitioner makes a uniform charge of one guinea for a visit. This we are glad to see the *Eastern Morning News* considers by no means excessive. However, our contemporary goes on, "In some villages the difficulty is surmounted by private persons having a knowledge of physic and surgery. At Octon a large farmer is a qualified M.D., and at Langtoft the vicar can attend all ordinary cases, and make a poultice, and lance an abscess, &c." We have nothing to say as to the qualified M.D. except that as his name does not appear in the Medical Directory for 1899 under "Octon" we are unable to ascertain from what university he obtained his degree; but we feel compelled to say that the Vicar of Langtoft is treading upon dangerous ground. He can do good work if he impresses upon his sick parishioners the advisability of seeking trained medical aid or of the necessity for fresh air in the sick room. He may not do much harm with a poultice if its application is not the signal for deferring the seeking of the services of a medical man, but if he is in the habit of opening abscesses he will one day come to grief. The incision of an abscess is a thing in no way to be undertaken by unskilled hands, for it is an operation which for its safe performance demands a considerable amount of anatomical knowledge and we should counsel the reverend gentleman to refrain in future. But the kind of clergyman who does real mischief is one such as the writer of the following letter, addressed to the editor of the *Record* and published in the issue of that paper for Jan. 5th under the heading "Influenza: a Remedy":—

> SIR,—Now that the epidemic of influenza is gaining ground I strongly recommend an invaluable remedy I saw in your columns about three or four years ago, which a clergyman advised. It is to be had from Messrs. F. C. Calvert and Co., Manchester, and is called "No. 1 Medical Phenol," price 1*s.* 6*d.*, or with postage 1*s.* 9*d.* Take three drops with two tablespoonsful of water for a dose—only take three doses in all—with four hours between. Half the quantity for a child. In most cases it makes a perfect cure in a day. Shake the medicine well. I have known 50 cases cured in my parish with it. SPENCER J. COMPTON.
>
> South Creake Vicarage, Fakenham, Jan. 2nd.

This kind of letter does infinite harm. It is not true to say that nine minims of carbolic acid taken in three doses will cure influenza or any other infectious fever in a day. The advice is dangerous not only to the patient himself by leading him to think that he has done everything necessary for his own welfare, but it also leads to his not improbably infecting others. Unfortunately in this land of freedom any person, however ignorant, may prescribe and any other person, however foolish, is quite at liberty to take such prescriptions; and the spread of education seems as yet to have done little in making the masses wiser. The Dowager Countess of Southdown who drugged her tenants with Podger's pills lived in an unenlightened age. The vicar of South Creake would be well advised if he attended to his own business. As a rule in a village, as we have said upon a former occasion, the vicar and the medical man may work well in coöperation, and as long as this sort of coöperation has careful regard for the privileged nature of much that is told to the members of both professions the result is for the public good. But when it comes to the members of one profession usurping the functions of the other nothing but harm can follow. In a town the evils are somewhat less obvious, but in a village where very likely the clergyman and the medical man are the only two liberally educated inhabitants the evils of a dual medical control are grave.

THE DEARTH OF LOCUM-TENENTS.

WE have been informed from various quarters that owing to a multiplicity of causes, such as the action of the General Medical Council in forbidding the further employment of unqualified assistants, the war in South Africa which has absorbed the services of many civilian medical men, and the existence of an epidemic of influenza, there is a great dearth in the supply of medical men willing to act as locum-tenents. This being so, we regret to learn that some men who are available for such posts are with short-sighted policy taking advantage of the present distress to exact large fees. This is not as it should be. We have ever maintained that the labourer is worthy of his hire, but when we hear of locum-tenents demanding excessive remuneration on the plea that their services are greatly in demand and that demand is in excess of supply, we must enter a protest. The locum-tenent of to-day will be, or at any rate hopes to be, the practitioner of to-morrow, and he should be prepared to look at his opportunity rather from a broad professional point of view than from his own sectional point of view. We do not for one moment suggest that all young practitioners who seek for the post of a locum-tenent are acting in this manner, but it must be remembered that in a profession such as ours the defections of individual members are visited upon the profession as a whole, and therefore we earnestly trust that the few who are in error will speedily be brought to see the foolishness of their present course of action.

MATERIA MEDICA LABELS.

WE have received from Mr. H. K. Lewis, of 136, Gower-street, London, a book of materia medica labels adapted for public and private collections. The labels are arranged in two divisions, the first division comprising chemical materia medica (alcohols, alkaloids, sugars, and neutral bodies), and the second division comprising with a few exceptions substances of organised structure obtained from the vegetable and animal kingdoms. The whole series is compiled from the British Pharmacopœia of 1898 and other sources. The characters are clear and where the formula is possible it is given. The labels are of a convenient size and the gum is uniformly distributed and free from those objectionable qualities which frequently characterise adhesive matter. The compilation should be very useful. The price is 10*s.* 6*d.* the book including nearly 500 labels.

"A SAD AND URGENT CASE."

To the Editors of THE LANCET.

SIRS,—The following additional subscriptions have been received for this fund. The list will remain open until Jan. 27th only and subscriptions may be sent to Dr. H. Macnaughton-Jones, 141, Harley-street; or to

Yours faithfully,

WILLIAM H. BOURKE, M.D. Brux.

THE ORGANISATION OF THE PROFESSION: SOME SUGGESTIONS.

To the Editors of THE LANCET.

SIRS,—Re the query of your correspondent "Hon. Secretary" in THE LANCET of Dec. 30th, 1899 (p. 1870), in which he asks for particulars of a Provident Medical Association to be managed solely by practitioners, you refer him to the excellent and invaluable articles in THE LANCET on the "Battle of the Clubs," &c. These are, indeed, invaluable and will amply repay careful study by anyone interested in the question. The articles above referred to deal with a series of more or less local provident associations; the idea that your correspondent apparently has is for a more comprehensive scheme which shall be more generally applicable and embrace more than the particular district in which it happens to be started.

For some two years past I have been (with the help of a solicitor of considerable experience in organisation and an accountant) endeavouring to frame the constitution, rules, and directions for working just such a scheme under the name of "The Public Medical Service," and I hope that it will very shortly be ready for publication. If your correspondent or others interested will communicate with me either through your columns or privately I shall be happy to answer any brief and direct queries upon the subject. Briefly the principles upon which the scheme has been drawn up are that "The Public Medical Service"

shall be managed and controlled solely by registered medical practitioners; that every medical practitioner who agrees to conform to the rules shall be eligible to act on the medical staff; and that there shall be a wage limit and no canvassing. The service is to be managed by a central executive council annually elected from and by the general body of members. The rules are so drawn that they may apply as far as possible to any district. Power is delegated by the executive council to members residing in the various districts to carry on the service in that district within the powers delegated to them by the rules and to elect their district officers. The district officers are chairman, secretary, and treasurer. The district committees engage collectors as required. The collectors are absolutely forbidden to canvass. Members of the medical staff must sign an application form and undertake to obey the rules. Every registered medical practitioner in the district is eligible to join the medical staff and is *ipso facto* a member of the district committee upon being admitted upon the medical staff. The district committees carry on the business of the service in the district within the powers delegated to them by the rules. The questions of practitioners residing upon the borders of one or more districts, and other complications that may arise, have as far as possible been considered and provided for. The question of dispensing by chemists has been considered and rules have been framed should a district desire to adopt that method. Patients are admitted by the medical staff upon written application. Subscriptions of patients are payable according to their weekly income. No reduction is made for women or children as such, but members of a large family with a small joint income may be admitted for a smaller premium each than if they joined as separate entities. The actual premiums to be paid according to the income have been the subject of most careful consideration by a small committee of medical men. The classification has been agreed upon, but it is felt that the actual sums should not yet be fixed. Certain extra fees are payable by the patient to his medical adviser—for example, confinements, consultations, small-pox in the unvaccinated, certain cases under the Workmen's Compensation Act, &c. All extra fees are payable to, and retained by, the medical man. Subscriptions are paid to the collector, by him to the district treasurer, and thence to the head office. The books close quarterly, when the money is returned to members of the medical staff according to the actual amount received from their patients less expenses and contribution to the reserve fund. By an application of the card system the accounts of each member of the medical staff and of each district are kept separate with a minimum of clerical work. The card system has been adopted for keeping the records of patients and a modification of it for keeping the accounts; by this means the clerical work at the district and the head office is reduced to a minimum. Patients may transfer themselves quarterly from one practitioner to another or from one district to another after giving due notice. To enable them to do so they must obtain a certificate of transfer which states that they have paid up all subscriptions and arrears due to the medical man they are leaving. This certificate is taken to the new medical attendant and by him sent to the proper quarter. The wage limit and weekly subscriptions are subject to periodical revision which need not necessarily be retrospective. By the system adopted it will be possible to trace a patient from place to place and thus to a large extent prevent fraud. To be successful when started the scheme must be worked upon broad principles. The object of the executive council should be to induce all practitioners to join either as active or honorary members, their especial aim being to offer a substitute to practitioners to replace the medical aid appointments already held by them. It would be difficult to ask a man to sacrifice perhaps half his income unless one could offer some substitute. Central control is essential to ensure uniformity in the working of the district committee and to keep the service an individual entity and not a series of irregular small associations. The government must be democratic; this will be secured by the annual election of the whole council, sufficient continuity of procedure being secured by the right of the council to nominate—as from the council—and recommend their successors for election, nominations being also received from the general body of members. The details are innumerable, nor would any useful purpose be served by attempting to include more of them here. So far as possible the above principles have been carried out in the proposed rules and directions for working.

I shall be happy to receive communications from practitioners interested and to answer any short and direct queries upon the proposed scheme, and especially to know what support is likely to be forthcoming from the profession should such a scheme be propounded.

I am, Sirs, yours faithfully,

MURTAUGH HOUGHTON,

Hon. Secretary to the East Suburban Medical Protection Society, Limited; Member of Council of the Corporate and Medical Reform Association.

York-road, Ilford, Jan. 7th, 1900.

"THE MACKEY FUND."

To the Editors of THE LANCET.

SIRS,—I have received the following subscriptions on behalf of the widow of the late Mr. Stephen Mackey:—Amount previously reported, £13 8*s.*; Sir Joseph Ewart, M.D. St. And., F.R.C.P. Lond., Brighton, £1 1*s.*; Dr. Mouillot, Harrogate, £1 1*s.*

I am, Sirs, yours faithfully,

LEONARD C. DOBSON, M.D. Lond.

59, Addison-gardens, Kensington, Jan. 10th, 1900.

Enquirer.—Under certain circumstances—i.e., where there is good collateral security—an agent might consider such a proposal, but under those circumstances whoever acted as security might as well act as principal. The proceeding is for obvious reasons quite unusual and the collateral security would have to be very sound. For who is to ensure that the medical man will live to return the advance, or will have health to continue in practice, or will work the practice in such an efficient manner that here will be each year a surplus from which to repay the money lent?

H. A. B.—We cannot decide upon the comparative merits of the degrees and diplomas mentioned. Each is a good qualification and for each nowadays work of a fairly high standard is expected. An M.D. degree has the obvious use in general practice of giving its possessor an academic right to the popular title which he will anyhow receive; but the special department of work which our correspondent contemplates taking up is daily becoming more purely surgical.

J. W.—We do not recommend practitioners, specialist or other. Our correspondent can obtain from his medical man the names of the gentlemen whom it might be advisable to consult, if a consultation is required. The complaint is unfortunately an obstinate one in some of its forms.

H. J. P.—We do not recommend practitioners.

ERRATUM.—The death of Surgeon-Major Alexander Gibb Grant, which appeared under the heading of "The Services," in our last week's issue should read, instead, "Surgeon-Major Alexander Grant."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Leicester Free Press, Westmorland Gazette, Market Harborough Mail, Daily Mail (London), New York Sun, Birmingham Daily Post, Morning Herald, Nottingham Daily Guardian, Scotsman, Times of India, Pioneer Mail, Citizen, Builder, Architect, Liverpool Daily Post, Sanitary Record, Bristol Mercury, Brighton Gazette, Yorkshire Post, Birmingham Daily Gazette, Eastbourne Gazette, Hereford Mercury, Sheffield Daily Telegraph, Malton Gazette, Glasgow Herald, Local Government Chronicle, Hertfordshire Mercury, Mining Journal, Reading Mercury, City Press, Denbighshire Free Press, Carolina Spartan, Local Government Journal, Surrey Advertiser, Yorkshire Herald, Sportsman, Manchester Courier, Southampton News, British Dental Journal, Naval and Military Record, Drogheda Conservative, Batley News, Kentish Express, Fife Herald, Alliance News, Leighton Buzzard Reporter, Woburn Reporter, Wakefield Herald, East Sussex News, Todmorden Advertiser, Halifax Courier, Leeds Mercury, Norfolk Daily Standard, Eastern Daily Press (Norwich), &c., &c.*

METEOROLOGICAL READINGS.

FRIDAY (19th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. D. Grant: Consultation. (Eye, Ear and Throat.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1899, which was completed with the issue of Dec. 30th, and the Title-page to the Volume, were given in THE LANCET of Jan. 6th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1899 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied, Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Mr. D. Ainley, Halifax; Association for Supply of Pure Vaccine Lymph, Lond.; A. D. Z., Leeds.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

Two Clinical Lectures

ON

THE USE OF MASSAGE IN RECENT FRACTURES AND OTHER COMMON INJURIES.

Delivered at St. George's Hospital on Jan. 30th and Feb. 27th, 1900,

BY WILLIAM H. BENNETT, F.R.C.S. ENG.,

SURGEON TO ST. GEORGE'S HOSPITAL; MEMBER OF THE COURT OF EXAMINERS, ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC.

LECTURE I.

Delivered on Jan. 30th.

GENTLEMEN,—It is now more than two years ago since I called attention to the use of massage in recent fractures,[1] a treatment which had previously received too little attention in this country. After having had some experience of it I then came to the conclusion that, rationally practised, this treatment was probably the best method which could be used in ordinary fractures, both simple and compound, when the circumstances of the practitioner and of the patient permitted its adoption. The result of that communication was, I believe, a considerable increase in the use of the method. It has been employed freely in St. George's Hospital with excellent results. Latterly, however, there has been some falling off in its use—not because there is anything wrong in the principle of the method or with its results, but because it is at times difficult to keep the necessary number of dressers, who of course are constantly changing, sufficiently instructed in the details to enable it to be safely carried out. I have, therefore, thought that it might be useful to devote some attention to a practical description of the way in which the treatment should be applied.

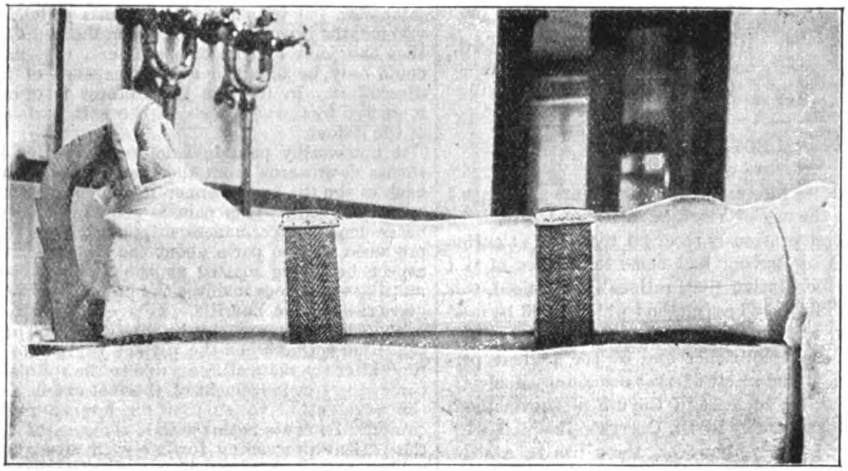
I do not propose to confine my remarks altogether to massage in fracture, as I think it will be useful to deal generally with the subject of the legitimate use of rational massage in common surgical injuries. In other words, I shall try to say something useful about the treatment of recent fractures, of dislocations, and of sprains and bruises by the same means. It is possible that I may be able to say something about the treatment of each of these varieties of injury—at all events, I hope the time spent in considering the matter will not be entirely wasted.

THE TREATMENT OF RECENT FRACTURES BY MASSAGE.

Most of you know that the real difficulties and disappointments in cases of fracture, supposing they are treated in the ordinary way, often commence after the union has taken place and the patient begins to think of getting about. There are, of course, initial difficulties in connexion with the "setting" of the bones and in the subsequent keeping of the fragments properly in place, but these, as a rule, cause no great trouble provided they are intelligently met. The difficulties in the later stages are mainly pain and stiffness, which frequently require a long and trying course of massage and passive movement before the patient is able to get about with comfort or to follow his occupation and which sometimes lead to permanent crippling. In the case, for example, of a fracture of the leg treated in the ordinary way by having been placed in splints or in plaster-of-Paris, or by some other contrivance of that kind, for a long period, say from six to eight weeks, you will find that when the splint, of whatever kind it may be, is taken off and the patient begins to walk about or tries to walk about, complaint is frequently made of intolerable pain about the ankle and sometimes across the sole of the foot. The ankle is quite stiff, the knee may also be stiff, and the muscles are wasted so that the leg may be little more than bone and skin. Supposing, however, that the case has been treated rationally by massage from the beginning, you will find that the patient is afflicted with none of these troubles; the ankle is not stiff, there is no pain such as I have mentioned, and the muscles are not wasted, because in the massage treatment they are developed; in fact, when the patient begins to get about the ankle is free and supple and the muscles are practically in the same condition as those of the sound limb. These are obvious and great advantages. The reasons of the discomfort which patients suffer when the treatment has been conducted upon classical lines are easily explained. The stiffness is due to the fact that in consequence of the limb having been placed in an immovable splint for a long period the joint included in the splints becomes, as a matter of course, stiff. If, for example, a perfectly healthy ankle-joint were put into a plaster-of-Paris splint for six weeks or two months it would be found upon the removal of the splint that the joint had become stiff and that natural mobility could only be obtained at the expense of pain and great discomfort. In fracture the stiffness is of course infinitely increased by the adhesions of the soft parts around the seat of the lesion.

A noteworthy pain in fracture of the leg is that which shoots downwards from the seat of the fracture along the back of the leg to the inner malleolus and thence into the sole of the foot. This pain is sometimes most acute and at times leads to permanent crippling; it is due to neuritis produced by the parts about the fracture on the posterior aspect becoming matted at the level of the injury; this matting sometimes involves the posterior tibial nerve and so gives rise to the neuritis. This condition is no imaginary one since I have proved it by dissection.[2] The result of this condition is that when the patient begins to try to use the limb after the mere stiffness due to the splints has been overcome, any free movement of the foot causes a dragging upon the adherent nerve so that an intense neuralgic pain is caused. So acute is this pain in some cases that it prevents the patient proceeding further with attempts to get better movement. People are therefore sometimes seen walking with stiff ankles after fractures of the leg which have been treated by persistent splinting, not because the stiffness cannot be overcome but because the pain on movement of the ankle is so great that they are unable to bear the necessary manipulation. All this trouble is preventable by the use of intelligent massage in the early stages of fracture In the early stage of fractures the main difficulty is, of course, as I said just now, connected with the setting of the bones, the difficulties arising in this respect being mainly three. One is the ordinary nervousness of the patient, which, of course, can only be overcome by tactful management or by the administration of an anæsthetic; the second is connected with the direction or other peculiarity of the fracture; and the third difficulty arises from muscular spasm, the result, no doubt, either of irritation of the muscles by sharp edges of bone or of direct laceration of the muscles themselves which in consequence become hyper-sensitive and excitable. I know of nothing more difficult to relieve under ordinary circumstances that the muscular spasm which comes on after the injury in some cases of fracture. Not only is it painful to the patient, but the constant muscular contractions frequently render the retention of the fragments in proper position almost impossible.

In the old times—and with some people it is even the custom now—it was sought to overcome this spasm by tenotomy, and since it is more commonly met with in the muscles of the calf than elsewhere, division of the tendo-Achillis was the operation most frequently performed for this purpose, because it was thought that division of the tendon would for the time being paralyse the gastrocnemius and soleus and would permit of the proper adjustment and retention in position of the fragments which could not be otherwise accomplished. It is not unusual after the reduction of a fracture with or without the aid of an anæsthetic—we will, for example, take the case of the leg—to find when the patient recovers consciousness that uncontrollable spasm occurs; the pain is acute, the muscular contraction is inevitable, and if the fracture is at all oblique the displacement recurs. Spasm of this kind is more efficiently controlled by massage than by any other plan, excepting perhaps prolonged anæsthesia by ether or narcotism by opium, alternatives which are obviously undesirable in a general way.



Assuming that massage in these cases of recent fracture is right—as I have no doubt it is—the next point for our consideration is the method of its application. There are, roughly, three stages in the process and each of these stages

[1] THE LANCET, Feb. 5th, 1898, p. 359.

[2] Ibid.

effects certain purposes. Naturally, the first thing in every fracture is to "set" the broken bones, by which I mean placing them in their proper positions. Nothing short of accurate replacement of the fragments in their proper positions should be regarded as a satisfactory "setting." The primary point, therefore, to be borne in mind in every case of fracture is that too much trouble cannot be taken in the first instance in getting the bones into position. With regard to the plan of fixing fractured bones in position by the use of screws, nails, pegs, wire, &c., I propose to say nothing here. The method may be under certain conditions a good one, but it obviously cannot be freely adopted by the ordinary practitioner, although it may produce excellent results in the practice of some of us.

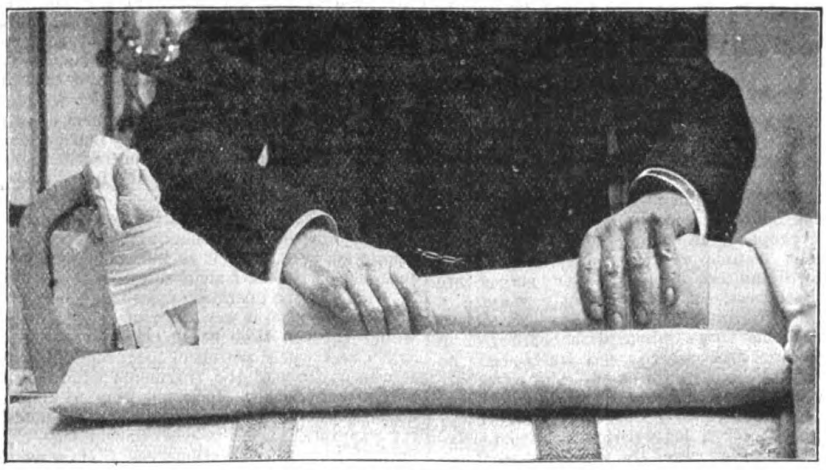


FIG. 1.

Massage in recent fracture of the leg. Stage 1: The fracture set.—The limb is secured on a back-splint, with a slightly oblique foot-piece, by bandages at the ankle and knee. Side-splints fixed by webbings or straps complete the fixation of the fracture.

swelling about the fracture; there is also a certain amount of muscular spasm. He complains so much of the spasm that unless something is done he can hardly lie quiet and certainly cannot sleep or feel comfortable. The ordinary method under such circumstances is to give a hypodermic injection of morphia, or, if the bones are not in precise apposition, to give an anæsthetic if that has not already been done. You will, however, find that unless the bones are grossly out of place—in which case you must at once rectify the defect—gentle massage over the fracture, merely a smooth upward movement of the hand which grasps as much of the circumference of the limb as possible, will in a very few minutes, in the majority of cases, practically relieve all spasm. You will sometimes find people who are suffering

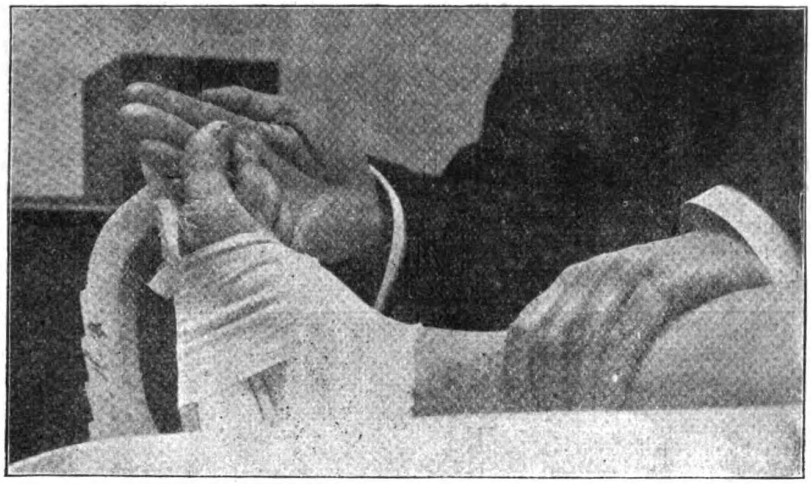
FIG. 2.

Massage in recent fracture of the leg. Stage 2: Immediate smooth rubbing.—Commence at any time, the sooner the better after the fracture has been "set." The straps fixing the side splints are unfastened and the splints are allowed to fall away from the limb. The knee is then steadied by one hand of the manipulator whilst smooth gentle rubbing from the foot upwards is effected by the other hand, which is made to grasp as much of the circumference of the limb as possible. The time required is from five to 10 minutes. The objects are the relief of muscular spasm and rapid absorption of effused blood, &c. At the end of this stage the side-splints are replaced, leaving the parts in the condition shown in Fig. 1.

Returning from this digression to the method of applying massage, let us suppose that this man before you has a broken leg, somewhere below its middle. He has come at once to the hospital and the fracture has been what is commonly called "set"—and as he has come here we will suppose it has been properly set. There is a good deal of from spasm to such an extent that they are crying out with the pain and who are certainly unable to get any peaceful rest, after a few smooth passages of the hand over the damaged part settle down comfortably; in some cases they will actually fall asleep while the rubbing is proceeding. This movement, however, must be done in the right way—

that is to say, with the flat of the palm of the hand grasping the limb very smoothly and uniformly in the way I show you (vide Fig. 2). You need not be in the least afraid of smoothing the limb over the fracture if you do it properly. Patients do not resent the pressure at all—in fact, they rather like it, as some of you know already from what you have seen in my practice. The first object, then, that massage effects in these cases is the relief of the pain due to spasm should it be present. The same smooth movement that I am now applying very gently over the swollen parts day the massage is employed, at first mainly to get rid of the effused blood round about the fracture. At the end of the third day, again, after practising this smooth massage for ten minutes, passive movement of the muscles and tendons at the back of the ankle and in the calf should commence. In order to effect this you begin very gently by moving the toes only. The foot is still bandaged and the splint remains in the way you see here. The hand is insinuated under the toes in the way I am doing (vide Fig. 3) and dorsal flexion of the toes

FIG. 3.



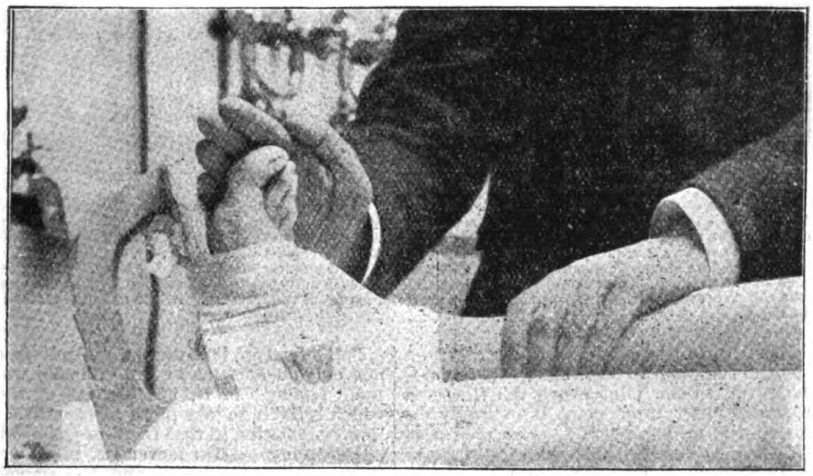


FIG. 4.

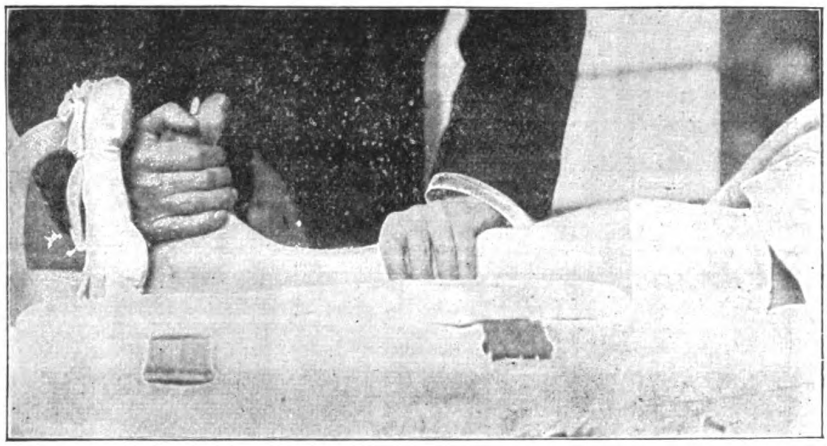
Massage in recent fracture of the leg. Stage 3: Commencement of internal massage.—After preliminary smooth massage as described in Stage 2 one hand of the manipulator is insinuated between the toes of the affected side and the foot-piece of the splint (**Fig. 3**). Dorsal flexion is then effected as much as possible by rotating the hand forwards and downwards (*vide* Fig. 4). This movement is repeated from five to ten times, the fracture being steadied by the grasp of the other hand of the manipulator. The date of the commencement of this stage may be any time after the second day. The objects are early slight movement of the flexor tendons at the back of the ankle to prevent adhesions. Movement of the toes separately instead of *en bloc* may be substituted at discretion. At the end of this stage the side-splints are replaced as in Fig. 1.



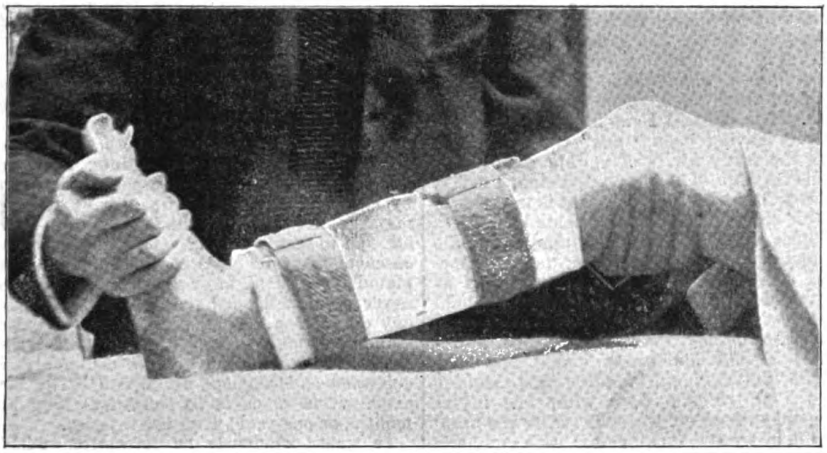
immediately about the fracture will also bring about absorption of the effused blood with extreme rapidity, so long as the rubbing is smoothly and carefully carried out. The splints used for the treatment of the fracture, you will note, consist of a back-splint with an oblique foot-piece and two straight side-splints, the latter secured by straps so that they are easily loosened (vide Fig. 1).

Immediate muscular spasm having been allayed in the manner indicated the side-splints at the end of two or three days are loosened and the limb is left exposed on the back-splint as this man's is (vide Fig. 2), and every *en bloc* is made (vide Fig. 4). Every time the toes are bent in that way the flexor tendons are pulled upon and so a little movement is produced. The little movement thus produced in the calf accomplishes the beginning of what is called "internal massage," by which I mean that there is a little rubbing movement up and down of the deep muscles in the calf of the leg. This movement not only stimulates the circulation but it makes sufficient movement to prevent immediate adhesions from forming about the fracture which would otherwise occur. The first passive movement then affects the toes; this is begun on the third day and

continued for two days—say, until the fifth day. If all goes well passive movement of the ankle may be commenced from the fifth to the seventh day. For this purpose the limb is allowed to lie quite comfortably, as it will do now, on the back-splint, the side-splints having been removed and the bandage around the ankle taken off, the bandage above the knee remaining undisturbed (vide Fig. 5). The foot is now firmly grasped with one hand and freely moved at the ankle-joint, the fracture being at the same time steadied with the opposite hand. After a few days the patient may be allowed to make voluntary movements of the ankle as it lies on the splint, the fracture being steadied by the surgeon's hand. Having arrived at this stage of the affair all fear of any adhesion about the ankle-joint or the parts behind the fracture ceases. It may happen in exceptional cases that the patient is so over-sensitive or the damage to the soft parts so extensive that the plan cannot be carried out with safety, but if employed with intelligence you will rarely find any case in which it cannot be profitably used. For the passive movements from three to five minutes at each sitting is sufficient. This is always preceded by a quarter of an hour's smooth rubbing by which the patient is generally made most comfortable. These processes are repeated day by day, extending at the end of the first fortnight to as much as half an hour for each sitting. At the end of a fortnight—a little more or less, according to the state of union—attention must be given to the joint above the fractured point. The joint below the fractured point is naturally the most important, because it is that which is most interfered with if adhesions form. At the end, then, of a fortnight or less, after having done what is necessary for the leg, the knee is subjected to passive movement. In bending the knee great care must be exercised, because the fracture being only a fortnight old, or a little more, is not in a condition of anything like firm union. The bending of the knee may be carried out in one of two ways. It may be done (1) by simply taking the leg, as you have often seen me do, with one palm under the limb just above the heel and the other grasping it under the thigh in the way shown in Fig. 6, and then lifting the knee from the splint. By degrees, as the case goes on, the knee may be raised more and more until at the end of three weeks it is bent up to a right angle. During the whole of these manipulations it must be constantly borne in mind that a recently broken limb is being dealt with. Although that is the plan I adopt in managing these fractures myself in private or when my masseuse is managing them for me, it is safer for hospital purposes at this stage, after the massage for the foot and leg has been finished, (2) to put on a pair of short side-splints, retained in position with straps or webbings, and then bend the knee and ankle in the way I show you (vide Fig. 6). This brings the treatment up to about the end of the third week after the receipt of the injury, and by this time in the majority of cases treated on this plan the fracture is nearly sound—not sound enough for walking but sound enough for the patient to be left without any splint. The patient can lie in bed if so disposed, or if the patient be a private one and prefers to be getting up and sitting on a couch or chair he may do so after having been provided with a case of poro-plastic or leather to be worn around the calf over the seat of fracture, as a kind of protection. At the end of three weeks you will find that complete ordinary muscle massage may be thoroughly carried out, in order to develop the muscles throughout the whole of the limb.

Such is the way in which any ordinary case of fracture of the leg may be treated by massage. The nearer the fracture is to a joint the more important is it that this massage should be carried out, for the simple reason that the nearer the fracture is to a joint the more likely is it that there will be subsequent pain and stiffness. Please understand that the use of massage and passive movement in these cases in no respect lessens the necessity for the point of primary importance in all fractures—i.e., placing the fragments at the outset in accurate position.

FIG. 5.



Massage in recent fracture of the leg. Stage 4: Increase of internal massage.—After the usual preliminary smooth massage the bandage fixing the ankle is removed, leaving the limb secured above by the bandage at the knee and at the seat of fracture by the grasp of one hand of the manipulator. The other hand is insinuated between the sole and the foot-piece of the splint and firmly but gently grasps the foot and makes passive flexion at the ankle as freely as possible five or six times without moving the fractured bones. The date of commencement of this stage may be any time after the fourth day but may in difficult cases have to be postponed as late as the eighth or even the tenth day. The object is movement of the ankle-joint and muscles at the back of the leg and the calf to prevent adhesions, especially at the posterior aspect of the fracture. At the end of this stage the splints are replaced as in Fig. 1.

Pott's fracture is always a difficult fracture, as you know, not only on account of the difficulty which often arises in the "setting" of it, but because of the matting of parts which is liable to take place afterwards. Once the bones are in good position in that fracture you need have no hesitation in beginning passive movement in two or three days after the injury at the latest, and the smooth massage may be commenced directly after the accident with great advantage. Because Pott's fracture happens to involve the joint there is no reason why passive movement should not be used immediately. Indeed, this is a strong reason for its adoption, for it is only by so doing that the avoidance of adhesion and stiffness can be with certainty accomplished (vide Fig. 7). I have described the case of a fracture of the leg because it is one of the most easy to manage. When managed on the lines I have described it will be found, if the practitioner will devote the time and the patient has the patience, that a better result will follow in fractures treated in this way than by any other plan, and that in the end the time which is occupied in the recovery of the patient is little more than half of that which follows the treatment by splints in the ordinary manner.

There is one fracture in which the effect of massage from the beginning is most remarkable—viz., intra-capsular fracture of the neck of the thigh-bone. So far as massage

of the part is concerned in a fracture of that kind it cannot be commenced too early. If it is started a few minutes after the injury it is not too soon. In such cases, as you well know, the pain is sometimes very acute, and the spasm is often almost continuous, the patient complaining bitterly of the jumping of the limb and the intense discomfort caused by the spasm. The suffering resulting from this kind than all the drugs and anæsthetics in the pharmacopœia. In a day or two let passive movement be commenced. Have no anxiety about the union, your main objects being to give comfort and prevent muscle-waste; upon the latter the ultimate utility of the limb will for the most part depend. The worst thing that can happen in cases of this kind is wasting of the muscles, which can be obviated by intelligent

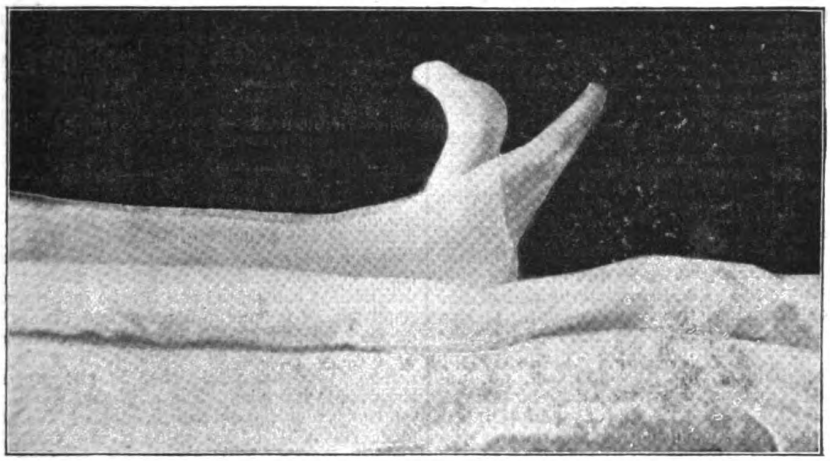


FIG. 6.

Massage in recent fracture of the leg. Stage 5: Increase of passive movement and commencement of complete massage.—The back-splint is now dispensed with, the fracture being fixed by means of side-splints straight or with foot-piece (Cline's). These having been removed the limb is laid on the bed or couch and complete ordinary massage is applied for 15 minutes. Unless the union is very firm the fracture is then fixed by two short splints or, better, by a moulded poroplastic or leather splint. Passive movements of the ankle and knee are then made in the manner shown in the figure. The flexion at the knee not only prevents stiffness of that joint but allows more free internal massage by relaxing the calf muscles. The date of commencement may be any time after the fourteenth day, according to the state of the union.

the spasm can be removed very rapidly by smooth rubbing of the sort I have described. In such a fracture you need not trouble about adjustment of the fragments. Bony union you know will not occur and, failing that, the indication is to obtain as useful a limb as may be. The object in view should be to get a moveable and painless limb with the muscles as strong as possible. No splints should be used. massage. This, then, is the treatment under ordinary circumstances which I strongly commend to your notice in such cases. The use of a splint should be altogether avoided, smooth massage should be commenced at once, passive movement should follow quickly, flexion and extension should be effected by lifting the knee from the bed in the way I show you, and rotation movements should be the

FIG. 7.

Massage in recent fracture of the leg, showing the amount of voluntary movement at the ankle in a severe case of Pott's fracture two weeks and three days after the injury. When the patient was admitted, immediately after the accident, the foot was displaced completely outward, the transverse horizontal plane of the sole being vertical. The use of all splints was discontinued in the third week.

Splints in such cases tend to the production of bed-sores and promote the wasting of muscles. They do no good and they render the patient most uncomfortable. Therefore let these cases be treated by smooth rubbing at once and passive movement in 24 hours. A masseuse, or any person with a moderately soft hand, can give more comfort in a case of last to be practised. For the first three or four days let passive flexion and extension be done as often as the nurse can do it; no pain occurs if the limb has been previously rubbed smoothly and gently. In a week or two rotation may be used. Under no circumstances should any passive movement whatever be employed until the neighbourhood of the

ury has been subjected to a good smooth rubbing. You may use liniments or not, as you please, but it is the rubbing which does the good.

There are few fractures in the whole body which are followed so frequently, I suppose, by a certain amount of defective movement as Colles's fracture, the result almost entirely of the matting of the parts. Sometimes it is said that the defects which follow in Colles's fractures are entirely due to the alteration in the relations of the bones produced by the injury. In certain of the cases the bones are without doubt altered in their relations to one another but the cause of the want of movement does not, as a rule, lie with the altered bone relations. The cause of the want of proper movement is practically always adhesions and nothing more, and if these cases are treated intelligently by massage from the first there need be no fear of defective power of movement. The method I use in such cases is as follows:—The fracture having been "set" the forearm is placed upon one of the many kinds of splints which have been devised for this fracture—Carr's splints being, I think, on the whole the best; but the kind of splint is immaterial so long as the anterior splint is placed well behind the bases of the fingers. Before the back-splint is applied gentle smooth rubbing should be used, the patient being immediately told to flex and extend the fingers as much as possible and as often as possible. The back-splint should from the first be removed daily for smooth rubbing. In two or three days a little gentle backward passive movement at the wrist should be made whilst the part lies exposed on the anterior splint after the smooth rubbing. In from four to six days after the injury the part should be gently lifted off the splint after the usual smooth rubbing and held by the manipulator with one hand firmly grasping the fracture area whilst the other hand flexes and extends the wrist a few times in succession. This is repeated daily, the amount of movement increasing gradually as time goes on. In a fortnight the patient may be allowed to make the movements freely of his own accord after he has been provided with a poroplastic or leather splint for the wrist which is easily removed and replaced. Ordinary complete massage is at the same time commenced daily. At the end of three weeks all splints may be discarded, the arm being carried in a sling for another week only.

Again, let me impress upon you the fact that the most important practical point to be borne in mind in connexion with passive movement in all cases of recent fracture is this: *passive movement should always be preceded by smooth massage which soothes the irritable muscles so completely that movements of the most complete kind are readily carried out without exciting muscular contraction of a harmful kind.* If, on the other hand, passive movement is abruptly attempted without preparing the muscles by previous smooth rubbing violent muscular action generally occurs which is not only painful to the patient but tends to throw the fractured bones out of place. There is, I am sure, no axiom in surgery which is more sound than is this: In all cases in which passive movement is practised smooth muscle massage should precede the movement.

Another set of fractures which can be treated by this method with a result which, speaking generally, surpasses that of any other plan are those occurring in the immediate neighbourhood of the shoulder-joint. The difficulties under ordinary circumstances of dealing with such fractures are too well known to require comment. I am now referring to fractures of the extreme upper end of the humerus and of the scapula close to, or involving, the shoulder-joint. It is a matter, I suppose, of common knowledge that such fractures are followed much more frequently than some people suppose by stiffness of the shoulder-joint. It is, in fact, not uncommon to find upon examining a patient at a long interval after a fracture of this sort that the shoulder-joint is quite fixed, although the patient may be ignorant of the fact. Many patients who have sustained an injury of the kind I am now discussing complain continually of acute pain in attempting to raise the arm to a right angle from the body. In the case of the majority of patients who complain in this way an examination will show that the scapula in the movement mentioned moves with the humerus and that movement in the shoulder-joint is practically *nil*. In fact, a considerable proportion of people who have sustained this kind of injury, especially if the lesion has been treated by means of continuous splinting or fixed apparatus, never regain free movement in the joint. The method that I use, because it has given me the best results in all these fractures about the shoulder in the immediate vicinity of the joint, whether the lesion is of the humerus or of the scapula, is to commence smooth rubbing in the ordinary way *at once*. From the beginning of the case I use passive movement very gently indeed. One hand is placed on the shoulder, gripping the part as a whole. This fixes the shoulder girdle. To-and-fro movements of the arm are then gently made, especial care being taken to avoid rotation. If rotation is made movements between the fragments are liable to follow freely, and so union may be delayed or prevented. You need have no fear of harm coming from antero-posterior movement. At the end of three or four days gentle abduction from the side of the trunk is commenced; at the end of a fortnight circumduction may be gently carried out. Rotation should not be attempted for at least a fortnight, after which rotatory movement should be daily made. For these fractures near the joint I do not use splints, excepting a protective shoulder-cap of leather or poroplastic felt retained in position by straps so that it can readily be removed for the daily massage, nor do I use pads in the axilla. The arm is merely allowed to rest in a sling. By this method the treatment of cases of fracture close to the shoulder-joint may be completed in a fortnight or at the most three weeks, and I have never seen such good results attained in so short a time by any other plan. If in such cases the parts are confined in splints for long periods a stiff shoulder-joint follows, as I have already said, much more commonly than is generally supposed—a statement which can easily be verified by the examination of cases so treated at long periods (say nine months or one year) after the injuries.

It would obviously be impossible within the limits of lectures like these to give the details of the treatment of each kind of fracture, but the examples I have described give a fair idea of the principles of the plan which can readily be applied by any intelligent person. It is a method of treatment which must be conducted with discretion. In compound fracture it is not always practicable in the early stages, but after the wound has healed it can be used as if the case were one of simple fracture, and in the earliest stages of many compound fractures there is no reason why passive movement of the joint most likely to be concerned should not be practised, although the fact that the manipulations cannot in these be preceded by the smooth massage places you at some disadvantage in such cases. In very young children, again, there may be difficulties in using the method in its entirety, but even in these cases it is quite curious how a frightened child with a fractured limb can be soothed by gentle massage of the part.

The great advantages of the treatment are: (1) the ease with which the patient is made comfortable by arresting the muscular spasm and so relieving the pain; (2) the effecting of rapid absorption of effused blood, &c.; (3) the prevention of the stiffness by obviating the formation of adhesions; (4) the prevention of muscle-wasting and the preservation throughout the case of the normal nutrition of the limb; and (5) the shortening of the time by at least half during which the patient is prevented from resuming the ordinary use of the limb.

The only real objections to the plan are, I think: (1) the difficulty which must often arise in carrying it out, as unless a competent masseur or masseuse is available the time required must be frequently more than the ordinary practitioner can spare; and (2) the fact that it is a treatment requiring so much intelligence and discretion in the mode of its application that it may be difficult at all times to find a person to whom it may be entrusted with safety when the practitioner is not prepared to manage the details himself. The objection which has been raised on the ground that movements of the fractured bones must result is of no value if the treatment is properly carried out, as the movement is then practically *nil* and certainly not enough to prevent union in any degree whatever. What the results of the treatment of recent fractures by massage in the hands of others has been I do not know, but so far as my experience is concerned the results are far superior to those obtainable in any other way. I am not acquainted, for example, with any other treatment by which the result depicted in Fig. 7 could be obtained in an extremely severe case of Pott's fracture. With increasing experience of the method my belief in it has steadily become more sure.

Two Clinical Lectures
ON
PRIMARY SYPHILITIC CHANCRES.

Delivered at the London Hospital on Feb. 16th and March 2nd, 1900,

BY JONATHAN HUTCHINSON, JUN.,
F.R.C.S. ENG., &C.,
SURGEON TO THE LONDON HOSPITAL, ETC.

LECTURE I.

Delivered on Feb. 16th, 1900.

GENTLEMEN,—You will see so many cases of primary chancre in the out-patient room and elsewhere in this hospital that it is unnecessary for me to weary you with the ordinary facts about them. But I may remind you that they occur in very different forms, of which the following are the chief. There is a primary syphilitic chancre or infecting sore which is nothing more than a raised papule with hardly any induration. There is a second and much more common form in which there is a disc of induration without ulceration. This disc of induration may vary in size from that of a lentil up to almost any size, even two or three inches across. It may, for instance, form a complete ring round the penis. The hardness has given rise to the name "sclerosis" which has lately been applied, especially by German and American writers, to all primary syphilitic sores, and I am sure it is a great mistake so to apply it. I cannot impress upon you too strongly that the induration of infecting sores may be only slight and not infrequently absent; and there is no doubt whatever that occasionally a man gets syphilis from what has appeared from first to last to be a "soft sore." The third common form consists in an actual ulcer having generally an indurated base. These ulcerating chancres are especially apt to occur on the under and inner surface of the prepuce, and at what is called the retro-preputial fold or furrow; in other words, concealed positions where septic organisms are apt to get at them. They are frequently accompanied by such complications as foul discharge, sloughing, and even sometimes hæmorrhage. Occasionally, in certain positions, primary chancres take the form of rings, for instance at the meatus of the urethra. Again, at the preputial orifice there is often an annular induration. You know that a primary syphilitic sore may commence with, or be preceded by, a soft sore or chancroid, which generally, at the end of three weeks, takes on induration, that induration being accompanied by enlargement of the inguinal glands. From two to four weeks after contagion—it is always advisable to date events from the date of contagion where you can ascertain it,—from two to four weeks after contagion the characteristic features of infecting sore should be present; in other words, at the end of three weeks from contagion you can usually decide whether a sore is going to be infective or not. The incubation stage, however, is sometimes strangely delayed. It may be up to six or eight weeks, but, as a rule, at the end of three weeks not only have the typical signs of an infecting chancre become manifest but the bubo is also well marked. That bubo, if carefully looked for, is found in something like 99 per cent. of the cases; it is hardly ever absent and is the most characteristic and constant of all the symptoms of syphilitic infection. Let me remind you of its chief features. The glands are indolent and painless, not adherent to the skin or matted to the deep tissues, and they are usually either almond-like in shape or "bulletty." The term "shotty" is often applied to them, but this does not convey so correct an idea as "bulletty"; and even when one grants that many of these glands are elongated like almonds they may be said to resemble the shape of the modern bullets. Remember, also, that the typical glands may be met with in one groin only or in both groins. If present on one side only it may be the opposite side to that on which the chancre is situated. Of this I have seen many instances, due to the crossing of the lymphatics.

Now, the character of the bubo is, as we said, one of the most remarkably constant features of syphilis. In an analysis of over 125 cases of infecting chancres which I shall refer to in only one did the bubo suppurate. In one other case it was inflamed and threatened to suppurate. But in the vast majority of cases the infecting sore is indolent throughout and does not either inflame or suppurate.

Another point which I shall have to refer to in detail is that in about 50 per cent. of cases of primary infecting sore there is, in addition to indolent enlargement of the glands, a cord-like thickening of the lymphatic vessels leading up towards the groin. Under the influence of mercury the induration of the sore, and to a less extent and at a slower pace that of the glands also, melts away. But if untreated the induration of a primary sore may last many months. There is a tendency for a chancre to re-indurate, that is to say, for recurrent induration to take place during the secondary stage at the site of the sore; and even in the tertiary stage, many years afterwards, there may be a recurrence of induration which is doubtless of the nature of gummatous infiltration at the site of the original chancre.

After these preliminaries we come to the question of the site of the primary chancre in men. I have carefully analysed the notes of 125 cases of infecting chancre under my care. In no less than 60 per cent. of these the primary sore—I am speaking of genital chancres—was either at the orifice of the prepuce, on its internal surface, or at what is called the retro-preputial fold or furrow; the relative proportion being about 35 per cent. at the furrow and 25 per cent. on the inner surface of the prepuce. Primary chancres in this part, either at the furrow or on the inner surface of the prepuce, are usually well indurated, sometimes excessively so, and being, in the majority of cases, concealed sores, and liable to septic contamination, a foul ulcer in the position is not infrequent with an offensive discharge and perhaps hæmorrhage. In 50 per cent. of the cases of chancre in this position there are indurated lymphatic cords running up towards the groin from them. But I want to impress upon you the immense frequency with which primary infecting sores occur in this region.

You know it is generally believed that syphilis is comparatively rare in the Jews. We do not know that they are, as a race, more moral than Christians, but the fact is undoubtedly true that Jews do not contract primary chancres in nearly so high a proportion as Christians. And you can understand the reason, for with the prepuce done away with and the skin, glans, and furrow harder than in normal cases, the risk of syphilitic infection is very much diminished. My experience, both at the Lock Hospital and at the London Hospital, where one sees a great number of Jews in the out-patient department, is that while they very often contract gonorrhœa, syphilis is a comparatively rare event with them.

Sometimes one sees a disc of induration running half-way or completely round the furrow. As in the case of chancres at the meatus and at the preputial orifice in phimosis the reason for this is fairly obvious. The fine lymphatics anastomose at these three positions, forming a circular network round which the virus is conveyed and produces annular induration.

Turning to the question of chancres on the outer surface of the penis—that is to say, from the pubes to the edge of the prepuce—we find 27 per cent. of the primary sores in that situation. They are often well indurated, but it is quite exceptional to find them forming foul ulcers with a septic discharge. Sometimes you meet here with the purely papular form. Lymphatic cords leading from chancres in this position appear, from my statistics, to be relatively infrequent; in only one of every four cases were they found. An interesting fact occurs in connexion with chancres on the outer surface of the penis, that is, you may find another chancre on an exactly corresponding position on the scrotum, and one cannot doubt that the inoculation has occurred from the first sore on to the scrotum, that the initial place has been the penis and then before the tissues have become protected against the virus of chancres inoculation has occurred on the scrotum.

We have now done with the frequent positions for primary infecting sores on the genitals and will proceed to the less frequent situations. Chancres of the glans penis are interesting because there you meet with what is called the "parchment chancre." Induration cannot be very extensive on the glans owing to the anatomical structure of the skin there. Chancres in this position were present in only 8 per cent. of

my cases. Primary infecting sores on the frænum, connecting the border of the glans and the rest of the penis, are very uncommon; I only make them out as 1 per cent. That is interesting because soft sores are frequent there. Over and over again, in cases of suppurating buboes in the groin you may have to search for the soft sore which has produced the infection, and very probably you will find it just at the side of the frænum, but in my experience syphilitic sores there are uncommon. Tears of the frænum are not uncommon and are apt to become the subject of unhealthy ulceration apart from syphilitic infection.

Then as regards the urethra. I am quite sceptical as to the occurrence of chancres further back than one inch from the meatus, and although constantly on the look-out for such cases I have never found an undoubted one. I have notes of some five or six cases only in which the chancre involved besides the meatus the immediately adjoining part of the urethra and the fossa navicularis. I will mention one in particular as being the most typical I have known. A man had gonorrhœa and eight months later he was exposed to further contagion and free purulent discharge followed. When he came to the hospital this urethral discharge was accompanied by a double inguinal bubo. The meatus was quite free and, of course, the presence of this double inguinal bubo, which is extremely rare in gonorrhœa alone, made one carefully examine the urethra. One could feel that the distal third of an inch of the urethra was involved, and on separating the lips of the meatus there was a crescentic ulcer, a true primary chancre, in the fossa navicularis. Such cases are uncommon and there is no proof that the syphilitic virus can get far back into the urethra during sexual intercourse. To recapitulate the result of the analysis of 125 cases of genital chancres in men, the majority occur in the inner surface of the prepuce and at the furrow—viz., 60 per cent. In a smaller number—viz., 27 per cent.—the chancre occurs on the outer surface of the penis; only 8 per cent. occur on the glans and 4 per cent. at the meatus and adjoining part of the urethra.

Of course, a primary syphilitic sore may be accompanied by one or more soft chancres, but apart from this comes the question, Are the primary infecting sores often multiple? You know that in books it is stated that one of the chief points in the diagnosis between a soft sore and a syphilitic sore is that the syphilitic sore is single and the soft sore is multiple. Do not attach too much importance to that statement. Now, of the 125 cases which I have analysed the actual infecting indurated sores were multiple in 20 per cent., or possibly rather over that figure. So that in one out of every five cases of primary infecting sores of the genitals you must expect two or three or perhaps even more indurated chancres. Of course, in cases where inoculation of the syphilitic virus has been performed at the same time at several points all those points develop indurated chancres. A syphilitic infant with mucous patches in its mouth may infect the breast of the nurse in many points, and Fournier quotes a case where there were 30 primary chancres on the breast from this cause. With that premise that they are not infrequently multiple, due to inoculation at the same time at different spots, we will note that they may be multiple from inoculation after the first chancre has developed. Let me give you a few instances of this. A woman came up to the hospital with a primary sore of the lower lip. We could not ascertain how it was obtained; in all probability it was through kissing. Six weeks later a second sore developed on the upper lip, exactly opposite the first one, and then it took on the characters of a primary sore. They were both indurated sores, with a smooth, glossy surface and scanty secretion. That is as clear a case of auto-inoculation as you could have. Then I have notes of several cases in which primary chancres have occurred on the penis and on the corresponding position of the scrotum where the two would come into contact. In another case there was a large primary chancre at the end of the penis, which the patient poulticed, and after two months a second chancre developed at the root of the penis, on the dorsum. At the end of seven months, when he first came for treatment, both chancres were typical, and he also presented a double bubo and a papulo-erythematous rash. A man who attended at the Lock Hospital had a very large primary chancre on his penis, the furrow being chiefly involved. He had to dress this sore himself, drawing the foreskin back several times a day. He was engaged in metal work and no doubt chips of copper frequently produced abrasions on his fingers. At the end of two months, during which time he was under constant observation and internal treatment with mercury, he appeared one day with a bandage round the right index finger. On inquiry he said he had injured the finger at his work and that the sore would not heal. It was found to be a typical primary sore. But this sore did not develop until six or seven weeks after the first sore on his penis, and he was under mercury at the time. It ran the usual course, became a large indurated sore, and he had a bubo in his armpit. Such a case is very striking and proves that whilst primary syphilitic sores are not, as a rule, auto-inoculable they undoubtedly may be so even many weeks after the first infection.

This leads one to the subject of extra-genital chancres—primary syphilitic sores on other parts of the body than the genitals. They are probably of much more frequency than is generally supposed. You ought, therefore, to be thoroughly familiar with the points about them, and you should be always on your guard lest you overlook a primary infecting sore on a part remote from the genitals. First as regards their occurrence on the hands. I saw not very long ago a medical man who had a primary chancre on each hand, acquired in reducing a para-phimosis (the patient must have had a syphilitic chancre at the time). There was no doubt infection of both hands at the same time, which is unusual. I have seen at least 20 chancres on the fingers of medical men or nurses who have been attending midwifery cases, the patient having syphilis. With regard to these digital chancres, there are some very good drawings in our museum showing the different forms which they assume. There is an excellent article by Mr. W. H. A. Jacobson lately published in the "Guy's Hospital Reports." These sores may occur on any parts of the fingers, but for an obvious reason they are most common towards the end. They usually have the form of circular granulating patches, with an edge of discoloured or pigmented skin, and they are usually somewhat raised. The induration may be only slight and they are, as a rule, painless, unless they happen to occur just round the nails (the peri-onychial whitlow). Another position is well illustrated in the drawing I now pass round. It happens to be a much larger granulating surface on the part where the skin is thin and delicate, on the dorsum of the first phalanx, going down into the cleft. Of that I have seen several instances. Occasionally one sees the lesions on the knuckles or higher up on the hand. I have seen knuckle chancres on the hands of both medical men and nurses. Let me impress upon you this fact, that although often suspicious in appearance there is nothing absolutely characteristic about these sores to show that they are primary chancres. There is, however, always marked glandular enlargement in the axilla and perhaps at the bend of the elbow as well, and this axillary bubo is as constant as that of the groin with primary sores of the genitals, and often even larger. Then these primary infecting sores may only arouse your suspicion because they will not heal like ordinary traumatic ulcerations. Long duration and failure to heal alone should elicit the suspicion of the medical man who is attending the case. I could relate to you case after case where primary chancres of the hands have been for weeks mistaken, even after the roseola or papular eruption has developed, with danger not only to the patient (the risk of the attack of syphilis being extra severe because treatment was not begun early), but also because of the chance of infection to other people.

Next as regards the lips. I saw some years ago an interesting case in which syphilis was acquired in a curious way. A young married lady was returning from India with her husband and when coming through the Suez Canal she was foolish enough to smoke cigarettes which had been made by Arabs and brought on board, and she developed a chancre on her lip from this cause. I saw her husband and he had no trace of syphilis about him. As you know, infection from pipes and cigarettes, though infrequent, has been proved by many instances. Lately a female, 60 years of age, came up to my clinic with a typical indurated chancre of the lip, acquired from nursing a grandchild, whom I also saw, with secondary syphilitic sores about its mouth. I have mentioned to you the case of a young woman who had an indurated chancre of the under lip and another on the upper lip from auto-inoculation. I have also mentioned the case of a man who denied—and with every appearance of truth—any risk of genital contagion for two years, but who presented a chancre on the mucous membrane of the cheek

accompanied by a large sub-maxillary bubo as well as a papulo-erythematous rash. I will not trouble you with chancres occurring far back in the mouth, as, for instance, on the tonsil, since my experience of these has been very small.

In ophthalmic work one occasionally comes across cases of chancres on the eyelids. I have also seen examples of chancre of the eyelids in students or medical men who, whilst seeing a great number of cases of primary syphilis, are apt to be careless and to rub the eyelids and thus introduce infection. There is in our museum a good coloured photograph from a case of mine showing primary chancre in the middle of the forehead in a boy with secondary eruption. This is certainly a very unusual site and we could obtain no evidence as to the method of contagion. I have, of course, seen a good many cases of primary chancre of the tongue, and whilst most of them were characteristic enough—circular or oval raised sores, with slight ulceration and well-marked induration—the following notes relate to a case which was a revelation to me because the chancre had only the appearance throughout of an insignificant white patch. The facts were these. A gentleman came under the care of another surgeon on account of such a patch on his tongue. He was told that it was syphilitic and was given mercury. He was not satisfied with this opinion and a few days later he came to me. All that he presented was a small white patch, not raised, on the outer side of the tongue, far back. It looked just as though the tongue had been touched with nitrate of silver. As the diagnosis was so doubtful we thought the patient had better wait, especially as he was a heavy smoker, and he was advised to give up mercury. He was seen independently by another surgeon, who gave him the same opinion, and neither of us suspected that the patch was a primary sore. Within about two months the patient developed a copious rash, undoubtedly of syphilitic nature, and then on the same side as that on which the patch appeared there was a large bubo of the submaxillary region which had appeared since his last visit. This case illustrates how deceptive a primary sore may be, and how difficult it is to be sure of infection in certain cases.

A case of primary chancre of the chin was interesting. A woman had two primary sores, one on each side of the middle of the chin. These were acquired in a manner which it is better not to discuss, but I mention the case because of its interest in other ways. The bubo was large and painful and slow to subside. The patient was at first treated by a surgeon with pills of green iodide. There is no doubt that the use of green iodide is largely responsible for the feeling sometimes met with amongst medical men and others against mercury given by the mouth. I never order green iodide because of all the preparations of mercury it is the most unstable and the most apt to cause diarrhœa and stomatitis, and therefore its administration has to be suspended. The production of stomatitis and diarrhœa is apt to prejudice the person against taking mercury by the mouth, and quite naturally. In this case the treatment had to be suspended, the chancres were very conspicuous, and the patient was much concerned about her appearance. She took three grains of mercury a day regularly for a year without the slightest ill effect, and beyond a slight annular syphilide she had no reminders of the disease.

Regarding extra-genital chancres on the lower limbs I have met with two particularly interesting cases. One was a primary sore on the heel in a boy who was an out-patient of the London Hospital. The lesion was right over the tendo Achillis—a most unlikely place, you would think, for infection. There was a well-marked bubo in the groin and he had a copious roseola. The history was as follows. He had had a scratch on the heel and had come up to the hospital to have this slight wound dressed. Whether the infection was conveyed in the receiving-room—which is possible seeing the number of syphilitic patients who come there—or whether it was done at home by using dirty dressings we cannot say. But certainly that scratch had become inoculated in some way with the syphilitic virus. Curiously, about that time I saw a chancre on the top of a patient's head, so that touches the two extremes of distribution in the body. I have notes of an interesting case of chancre of the thigh, a very uncommon position for such a lesion. The patient was a man, aged 22 years, who noticed after venereal contagion in June a sore on the front of his thigh half-way down towards the knee, "like a blind boil." It was painful, it ulcerated, and it then slowly scabbed. He came up to be seen in August—that is to say, three months after the contagion. He still had some soft sores on his penis and half-way down the thigh there was a raised purple disc, indurated and having a dry scab. This sore was two inches across. The glands were enlarged to a slight extent and there was a copious secondary eruption on the thighs, the arms, and the abdomen.

I have now briefly mentioned particulars of a good number of cases of extra-genital chancres under my own observation. Dr. Bulkley, in a most laborious and excellent work called "Syphilis of the Innocent," gives notes of 100 cases of extra-genital chancres which were under his own care. I do not know why he calls the work "Syphilis of the Innocent" because many of the patients described, so far from being innocent, were exceedingly depraved. That one surgeon should have observed over 100 cases of extra-genital chancre will prove to you how important is the subject.

It is interesting to recall the fact that in the early epidemics of syphilis, when the disease was brought over from America to Europe after the voyages of Columbus, this method of infection seems to have been very common. Before people knew the dangers of it it was spread widecast by drinking-vessels—which were not so plentiful as they are now—by spoons, and by other eating implements, and in all sorts of ways, apart from venereal contagion. At the present time probably the best places to see extra-genital chancres are the Paris hospitals.

A few words in conclusion on the subject of the indurated lymphatic cords which are often, as we have seen, present with primary infecting sores. If carefully looked for you will find indurated lymphatic cords in from 40 per cent. to 50 per cent. of the cases of primary syphilis. This will show you the importance of the matter, although it is not mentioned in any published description. They are most frequent in conjunction with chancres of the furrow or the inner aspect of the prepuce. One grants that they are less constant than the bubo, but sometimes they are better marked and of greater value in diagnosis. They seem to be in no way proportional to the number or size of the chancres or to the degree of the surrounding inflammation. As a rule, there is one indurated lymphatic cord running from the chancre, which usually tapers off towards the glans and can be often traced directly into the inguinal glands, but you may frequently find two, and in one case there were four, under the skin of the penis. They may be as thick as the stem of a clay pipe; they are often knotty, and occasionally they give rise to little lymphatic "abscesses," so-called, towards the root; a small collection of leucocytes and lymph forms and breaks, and the skin soon heals again. They may last into the secondary stage, but they usually disappear before the glands have subsided. Still, I have found them two or three months after infection. In one case there was a disc of induration, apparently lymphatic, right round the penis. The primary sore was at the frænum.

The question naturally arises, Are these indurated lymphatic cords ever found without primary syphilis? We have noted that they may be of great help in the diagnosis and that they are present in probably from 40 to 50 per cent. of the cases. I wish one could say that they are never observed without infecting sores, but though the exceptions are few they seem to be undoubted. Here is an example. A man had primary and secondary syphilis, and it was treated in this hospital in 1894 under one of my colleagues for four months. In 1895 the patient came to me at the Lock Hospital with gonorrhœa and phimosis, and he had a hard knotty cord going up to a swollen left inguinal gland. The cord persisted for a week or two.

I have notes of one or two other cases in which with inflammatory œdema of the prepuce and gonorrhœa indurated lymphatic cords were present, but these exceptions are so few that one is justified in attaching much importance with regard to the diagnosis of primary syphilis on the detection of these lymphatic cords.

SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.—The annual meeting of the Bath branch of this society was held on May 19th under the presidency of the Mayor. The report for 1899 stated that 106 cases had been investigated, 11 prosecutions had been undertaken (all of which resulted in convictions), and 84 warnings had been issued, the total number of children looked after being 217. The financial statement showed a favourable balance of £42.

PREVENTIVE INOCULATION AGAINST TYPHOID FEVER.[1]

BY ALEXANDER G. R. FOULERTON, F.R.C.S. ENG., D.P.H. CAMB.,

LECTURER ON PUBLIC HEALTH AND BACTERIOLOGIST TO THE MIDDLESEX HOSPITAL.

THE subject which I have chosen to discuss this evening, Preventive Inoculation against Typhoid Fever, is one which, I venture to hope, will have some sort of special interest for you who are for the most part engaged in the practice of that branch of medicine which deals more particularly with the prevention of disease. An additional reason which has influenced me in selecting this subject is the fact that it has at the present time a further interest for all of us, because of the extensive use which is now being made of the method in the hope of protecting in some degree our troops now serving in South Africa against a disease which is severely prevalent there and which is especially to be dreaded under the insanitary conditions which necessarily attend on the movements of the large army corps of modern warfare.

In the first place I will ask your patience whilst I refer in detail to the experimental work upon which this practice of preventive inoculation against typhoid fever is founded. If a suitable dose of a culture of bacillus typhosus of average virulence, such, for instance, as one obtained fresh from the spleen of a patient dead from typhoid fever, is injected into the peritoneal sac of a rabbit or a guinea-pig death will follow as a rule in from 24 to 96 hours, according to the exact amount of the dose injected and the individual susceptibility of the animal experimented upon. And, as a matter of fact, the individual susceptibility of different animals of these species to the action of this bacillus when cultures fresh from human sources are used varies considerably and is frequently a source of some difficulty in laboratory work. In the case of a guinea-pig weighing about 250 grammes a dose of one cubic centimetre of a 48 hours' old culture will generally cause death in about 48 hours. But by a simple passage of the bacillus through a series of animals the specific virulence of the culture may be considerably increased, and its action rendered more certain of result. This increase of virulence is obtained thus. A fatal dose of broth culture is injected into the peritoneal sac of a guinea-pig, a second guinea-pig is then similarly inoculated with the peritoneal effusion from the first, a third is inoculated from the second, and so on through a series of animals. With each successive inoculation it will be found that the virulence of the bacillus increases, so that gradually decreasing doses of peritoneal effusion are sufficient to cause death, and after the bacillus has passed through about 20 animals it will be found that the virulence is now so increased that 0·2 cubic centimetre of a 24 hours' culture in broth will almost certainly kill a guinea-pig within 24 hours. The animal dies with a general blood infection by bacillus typhosus, and the anatomical changes found after death may include engorgement of the spleen, the liver, and the kidneys, congestion and swelling of Peyer's patches, enlargement of the mesenteric glands, and serous effusion into the pleural and peritoneal sacs. A culture of virulent bacillus which will produce such effects as these is then used for the purpose of testing the degree of protection afforded to animals immunised by the method next to be described.

The immunisation is carried out by injecting into the animal selected several doses of a broth culture of the bacillus which has been sterilised by heat. Such a sterilised culture contains, in addition to the dead bacilli, various more or less toxic substances which the bacteria have formed in the broth during the course of their growth. And the degree of actual toxicity of such a sterilised broth will vary with the method of its preparation. Thus a highly toxic broth may be obtained by some such method as that of Sanarelli, which consists in incubating a highly virulent culture of the bacillus at 37°C. for one month, at the end of which time the broth is sterilised at 80°C. and the flask containing it is allowed to stand for some months at room temperature. The flask, after its neck has been hermetically sealed, is then heated for several days at 60°C., the sediment in the flask is allowed to settle, and the clear fluid is decanted. This clear fluid contains the soluble constituents of the bacilli together with the toxic substances formed during the development of the culture. A subcutaneous injection of about six cubic centimetres of this broth will kill a guinea-pig weighing 400 grammes in less than 20 hours. The symptoms following inoculation are those of rapid collapse accompanied by a fall in temperature, diarrhœa, and various nervous symptoms. After death there may be found a turbid effusion into the peritoneal sac, engorgement and softening of the spleen, petechial hæmorrhages into the mucous membrane of the stomach, and hæmorrhage into the cavity of the intestines. A somewhat less toxic broth than this is used for immunising purposes. A virulent broth culture is incubated for a fortnight at 37°C. and then sterilised at 100°C. For an average-sized guinea-pig four doses of five cubic centimetres each of this sterile broth are injected subcutaneously, an interval of two or three days being allowed to intervene between each dose in order to allow the reaction which follows one injection to pass off before the next is given. This having been done it will be found that the animal has acquired an active immunity against typhoid infection and will survive the injection into its peritoneal sac of at least 10 times that dose of actively virulent living culture which would inevitably prove fatal to an unprotected animal.

This condition of "active" immunity is characterised by certain changes in the animal's blood serum which will be found to have acquired three important new properties, which may be termed respectively agglutinative, protective, and curative. The agglutinative property is shown by the "clumping" or agglutination of the bacteria in a culture of the specific bacillus to which the diluted serum has been added, and with the serum of a well-immunised animal this agglutinative reaction will be actively manifested with a dilution of at least 1 in 1000. By virtue of its protective property the serum of the immunised animal when injected into another susceptible animal will confer on it a temporary or "passive" immunity against typhoid infection. Thus, if a dose of about two cubic centimetres of the serum be injected into another guinea-pig the latter will for a certain length of time afterwards be immune against an ordinarily fatal dose of virulent living culture. In a similar way the curative property of the serum of the immunised animal may be demonstrated by the following experiments. If an ordinarily fatal dose of living culture be mixed with about 0·5 cubic centimetre of the serum and then injected into a guinea-pig no result will follow. Or if the guinea-pig receives a full fatal dose of the living culture and then within about three hours a dose of the serum a similar curative effect will usually be manifested and the animal will usually survive the inoculation.

If we compare the serum of a patient who has passed through an attack of typhoid fever with the serum of the artificially immunised animal it will be found that the same agglutinative, protective, and curative properties are present; but in a lower degree as a rule in the human serum. Thus after an ordinarily severe attack of typhoid fever the agglutinative reaction is not as a general rule obtained with a dilution of more than 1 in 300, and very often fails before this dilution is reached; whereas with the serum of the immunised animal it is usually active with a dilution of 1 in 1000 and often after the dilution has been carried much beyond that point.

As regards the protective and curative properties Chantemesse and Widal have shown that the quantity of serum from a patient convalescent after typhoid fever which is necessary to confer a passive immunity against typhoid infection on a guinea-pig varies from two cubic centimetres to 10 cubic centimetres, as against a maximum of two cubic centimetres from an artificially immunised animal which will effect the same purpose. On these facts we are justified in assuming that a patient who has passed through an attack of typhoid fever has acquired an active immunity against typhoid infection. The direct proof of this is of course impossible, but for the reasons which I have given, and for other reasons which there is no time to discuss now, we cannot but assume that such is the case.

We have seen, then, that the blood serum of a patient who has passed through an attack of typhoid fever, and who has so far as we can judge acquired an active immunity against typhoid infection, possesses certain essential properties in common with the blood serum of a

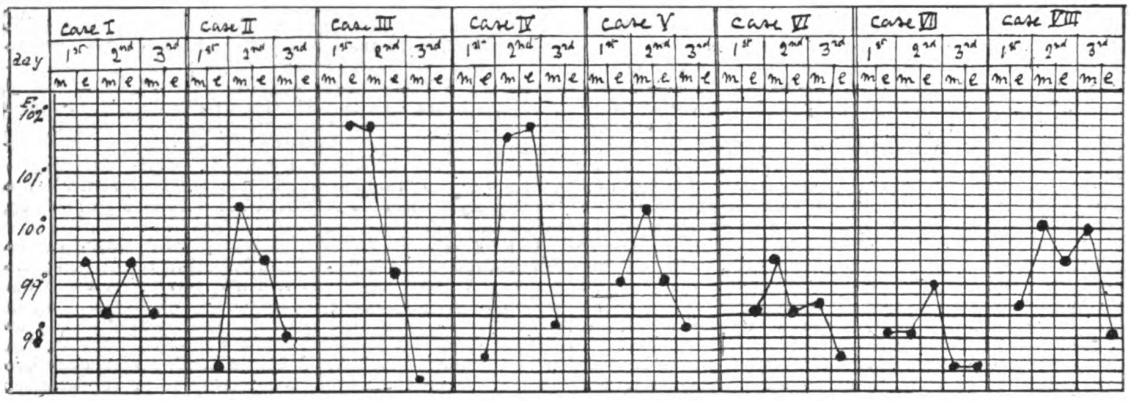
[1] A paper read before the Home Counties Branch of the Incorporated Society of Medical Officers of Health, April 26th, 1900.

guinea-pig which has received an injection of the dead bacilli, and which we know with absolute certainty has acquired this active immunity. In view of these facts the next question we have to consider is whether it is possible by employing the same method which is so successful in the case of the guinea-pig or rabbit to confer on man also an active immunity against typhoid infection. At the outset one must notice that a preliminary objection which would have been raised two or three years ago is now no longer valid. This objection would have taken the form that since typhoid fever as it occurs in man cannot be artificially produced in animals, therefore experiments on the latter do not apply. And so long as typhoid fever was looked upon as a disease essentially characterised by certain changes in the mucous membrane of the intestine this objection was without doubt a difficult one to answer, in spite of the fact that in one or two isolated instances a typhoid infection with actual ulceration of Peyer's patches had apparently been produced in the guinea-pig. But typhoid fever belongs to the class of infective diseases in which it has been possible with the advance of bacteriological knowledge to substitute for the older classification founded on anatomical changes a more accurate and comprehensive one founded on causation; and we now understand that the intestinal lesions, with all their immense clinical importance, are not an essential feature of typhoid infection in man, but are, so to speak, accidental lesions due probably to the fact that in man the bacillus usually infects by the intestinal tract; and, further, we know that not only is there in perhaps the majority of cases of typhoid fever a blood infection by the bacillus in addition to the enteric lesions, but also that typhoid fever may occur in man without any enteric lesions at all; and I think that the objections against argument from the guinea-pig to man would no longer be raised in this particular case.

The practical application of preventive inoculation against typhoid fever is, as you are all aware, entirely due to the work of Professor Wright of the Royal Army Medical School at Netley. And, whilst the utility of the method is still under trial, one cannot but pay tribute to the impartial and scientific way in which Professor Wright has dealt with the matter and to the care and minute attention to detail which have been observed in the preparation of the prophylactic fluid. In the procedure now recommended by Professor Wright a broth culture is used which after from 14 to 21 days' incubation at 37° C. has been sterilised by heat at 60° C.; lysol in the proportion of 0·5 per cent. is then added in order to prevent any accidental bacterial contamination after the broth has been sterilised. The amount used for human inoculation is two-fifths of the amount which would be fatal to a guinea-pig weighing 250 grammes. If a second inoculation is thought advisable a dose of about twice the amount of the first may be given after an interval of a week or so. The actual toxicity of different cultures varies, and sometimes considerably, but uniformity of dose is ensured as far as possible by the method of standardisation recently described by Wright and Leishman.[2] My own experience of the method is founded entirely on inoculations with sterilised cultures prepared as above with which Professor Wright kindly supplied me. The inoculations are made with an ordinary hypodermic syringe into the loose subcutaneous tissue either of the flank or of the back of the arm over the triceps muscle, the latter position being the more convenient if for any reason the person inoculated is unable to keep quite at rest during the next 48 hours or so. In my own cases I have always inoculated late in the afternoon and the patient has been kept at rest for the whole of the next day. The symptoms following the inoculation have been as follows. Towards the evening more or less severe constitutional symptoms may set in; thus there have been severe frontal headache, slight shivering, and in one case actual rigors and nausea, accompanied sometimes by vomiting. A tendency to syncope is sometimes present; it occurs within between four and six hours after the inoculation and very soon passes off, but is quite sufficient to render it necessary that the recumbent position should in every case be insisted on for some hours. All these constitutional symptoms, except perhaps a little headache, have invariably disappeared by the next morning—that is to say, within about 18 hours of the inoculation. The patient feels fairly well except for the local reaction which now begins to make itself felt at the site of inoculation. The local reaction results in a firm and painful œdema of the subcutaneous tissue with redness of the skin over it extending for about two inches round the puncture made by the syringe; there may also be redness of the skin extending for some little distance along the line of the lymphatics. Shooting pains may be present which radiate from the puncture in the flank principally upwards towards the pectoral region. The inguinal glands are enlarged and tender. By the following morning all the signs of local inflammation will have disappeared in nearly every case, and the completeness of the disappearance of what is sometimes a very intense local reaction in the short space of time is very striking. The only remaining effects of the inoculation felt by the patient are a general feeling of tiredness and a sensation of bruising and stiffness about the site of inoculation, although no trace of redness or œdema is now perceptible nor is there any tenderness on pressure. The temperature reaction is shown in these eight charts which, with the exception, perhaps, of the first, to which I will refer again, may be taken as fairly representative ones. Three different samples of the prophylactic fluid were used in these cases. The patients in Cases 1, 2, 3, and 4 were inoculated with one sample, those in Cases 5, 6, and 7 from another, and the patient in Case 8 from a third. For the purpose of comparison I have added the temperature charts of two rabbits which had received rather large immunising doses of a sterilised broth culture prepared by myself.

In most cases the immediate effect of the operation on the temperature seems to be a slight fall below the normal; the temperature soon begins to rise and attains its maximum within about 12 hours; it then falls rapidly and again sometimes to below the normal. The local reaction, as already said, may be severe, but since the inflammation caused by the prophylactic fluid is a purely aseptic one there need never be the slightest apprehension of suppuration, provided that the syringe has been properly sterilised and that the person inoculated is in ordinarily good health. If the inoculation has been successful it will be found that the blood serum has after a certain interval acquired the specific agglutinative property in a marked degree. A second inoculation may be thought necessary in some cases, a point to which I will refer again.

At present we know but little as to the details of the process which results in an immunity against an infective disease such as typhoid fever, and which may be set in action by this method of inoculation with a dead culture of the specific bacillus. Keeping the anti-typhoid inoculations more particularly in view we have the following data to work upon: (1) that the agglutinative power of the blood serum, the intensity of which we may take as being in some way a measure of the degree of immunity, does not appear until a certain interval of time has elapsed after the inoculation and then gradually increases up to a certain point; and (2) that the same agglutinative power may persist in the serum for a period of at least two years. The consideration of these facts will lead us to the conclusion that the protective substance or substances are not contained in the original dose of dead cultures, but are produced in the tissues of the individual after inoculation. Also in favour of this view is the fact that (as we have seen) a small dose of serum from an immunised animal will confer an immediate "passive" immunity upon another animal, a fact upon which the whole system of serum therapeutics has been based, while, on the contrary, it is found that the active immunity induced by inculation with a dead culture, although much more effectual and lasting, does not become manifest until a definite interval of time has elapsed. These facts are also in accordance with what is observed in the course of a case of typhoid fever in man. In an ordinary case a definite interval of time elapses after infection before the agglutinative power of the blood can be demonstrated and this agglutinative power, as a rule, then increases in intensity up to the time when the disease is brought to an end by a process of natural immunisation. We have, then, definite grounds for assuming that there is something contained in the original dose of sterilised broth culture which on inoculation causes such a reaction that the tissues of the individual produce a substance or substances which exert a protective influence against the living bacilli. The sterilised broth culture contains both dead bacilli and various substances which we may term generally toxins, but as to the exact



[2] Remarks on the Results which have been Obtained by the Anti-typhoid Inoculations and on the Methods which have been Employed in the Preparation of the Vaccine, Brit. Med. Jour., Jan. 20th, 1900.

nature of which we know very little. And the next question to be considered is whether the substance which is capable of calling forth this reaction on the part of the tissues is contained in the dead bacilli themselves or is one of the soluble toxic bodies formed in the broth by the bacilli whilst still alive. The answer to this question is not easily given, but the fact that an emulsion made by scraping off a surface growth of the bacillus on agar into a normal saline solution will produce the same immunising effect as a sterilised broth culture would suggest that it is some constituent of the bacilli themselves rather than any soluble extra-cellular toxin which is essential. Other facts, also, might be brought forward in support of this view.

I must now pass on to what is, after all, the most important point in connexion with this preventive inoculation against typhoid fever—Does it in practice realise what is hoped for from it? It may at once be said that this question cannot yet be answered, for the time which has elapsed since the inoculations were commenced is yet too short to enable us to judge fairly whether the almost perfect case in favour of this method which has been founded on the evidence of the laboratory is justified by the results obtained in actual practice. The first occasion on which the method was practically tested on anything like a large scale was during the Maidstone epidemic of 1897, when inoculation was offered to the medical staff, nurses, and attendants of the Kent County Asylum at Barming Heath. The main facts relating to the inoculations, with an account of the reaction of the blood of some of those who underwent the operation, have already been published by your President[3] and I need not refer to them now. The actual results were as follows. The first case of typhoid fever occurred at the asylum on Sept. 20th and the last on Nov. 10th. The total number of insane patients in the asylum was 1650; none of these were inoculated. The medical staff, nurses, and attendants numbered 130 in all, and of these 84 were inoculated between Oct. 5th and 9th. Amongst the insane patients who were not inoculated 88 cases of typhoid fever occurred, 74 cases before Oct. 9th and 14 cases after that date. Amongst the medical staff, nurses, and attendants 19 cases occurred, 15 before Oct. 9th and four cases afterwards, and the four cases thus occurring were all amongst those who had not undergone inoculation.

Professor Wright has lately published some statistics[4] bearing on the results of inoculations performed in India during the year 1898 and the early part of 1899. These statistics relate to 11,295 men belonging to various regiments stationed in different parts of India who had the opportunity of inoculation offered to them. Of the whole number 2835 elected to undergo the operation, whilst 8460 remained uninoculated. It was thus possible to observe the incidence of the disease on two classes of men, one presumably protected and the other not, both living under exactly the same conditions and both exposed to the same risk of infection. The results available up to the time of the publication of Professor Wright's paper were as follows. Of the 2835 inoculated, 27, or 0·95 per cent., subsequently contracted typhoid fever; of the 8460 uninoculated, 213, or 2·5 per cent., contracted the disease. The mortality figures applying to the

[4] On the Results which have been Obtained by the Anti-typhoid Inoculations, THE LANCET, Jan. 20th, 1900, p. 150.

total of 11,295 men are not at present available, as the returns from the different regiments did not in every case give the result of the illness. From the cases in which the issue of the illness was stated the mortality among the inoculated was calculated at two per 1000 and among the uninoculated at 3·4 per 1000. The case mortality was at the rate of 185·2 per 1000 among the inoculated and 103·3 among the uninoculated. These figures are undoubtedly in favour of the inoculated and might have been more strongly so had it been possible to have classed the men as "successfully inoculated" and "others," instead of as simply "inoculated" and "uninoculated." For with the methods in use at present the inoculation is unsuccessful in a certain proportion of the cases, and those who after inoculation do not give a good agglutinative reaction with their serum cannot for statistical purposes be fairly classed amongst the "inoculated."

Of the results of the inoculations which have been carried out in the case of the troops in South Africa it is too early to form any opinion. Mr. Osborn,[5] in commenting on the large number of cases of typhoid fever which have occurred among the troops, stated that at Modder River the disease occurred at the rate of 6 per 1000 among those who had been inoculated and at the rate of 9 per 1000 among those who had not. No stress can be laid on these last figures one way or another, but extremely valuable data will be available after the war when the complete returns are forthcoming. And in connexion with these statistics it is especially to be hoped that a thorough effort will be made to ascertain by means of the serum test what proportion of the soldiers who underwent the operation on the way out had really reacted to the inoculation. It has been said that the active immunity which follows the injection of a dead culture in animals takes some time to develop and that after the inoculation in man a definite interval elapses before the agglutinative property is manifested in the serum. It is not, therefore, to be expected that any protective effect will follow the operation immediately. I do not think, for instance, that protection would be afforded against an infection within about a week after the inoculation. In speaking of this I would particularly refer to Case 1 on the temperature chart. In this case there had been exposure to the risk of infection under rather exceptional circumstances both before and after the inoculation, the patient being one of four who contracted the disease by direct personal infection from one individual. As far as one could judge the patient must have been inoculated some five or six days after infection had occurred, and definite symptoms of the disease appeared on the eleventh day after the inoculation. The patient passed through an ordinary mild attack of the disease. It will be noticed that the temperature reaction after inoculation in Case 1 on the temperature chart differs very distinctly from the type occurring in Cases 2, 3, and 4, which were inoculated at the same time and from the same sample of serum.

At present we do not know exactly what length of time any protection afforded by the inoculation may be expected to last. In a certain proportion of cases, if we accept the persistence of agglutinative power as an indication of the persistence of immunity, the protective effect lasts for at least two years. By the kindness of Dr. Arthur Jackson, assistant medical officer to the Kent County Asylum, I had the opportunity in October last year of examining the blood of nine of those who had been inoculated just 24 months previously. The results obtained on testing the agglutinative power of the serum in these nine cases are shown in the following table which has already been published elsewhere.[6] Of the nine cases four had previously been tested by Dr. Tew[7] and two of them (Case 4 and Case 5) had given only doubtful reactions shortly after inoculation; the serum from the last five cases had not been tested previously.

From what I have said it will have been gathered that the immediate after-effects of an anti-typhoid inoculation may be distinctly unpleasant, and it is not suggested that these inoculations should be employed generally, but only for those who may be specially liable to the risk of infection. And among those to whom preventive inoculation is likely to afford most benefit are nurses in hospitals into which cases of typhoid fever are admitted, and soldiers who are serving in India and other places where this disease is most prevalent. And it need scarcely be added that if inoculation is advisable for a nurse or a soldier the younger the individual may be the more strongly is inoculation to be advised. And it must not be forgotten that these two classes which I have mentioned include those who are not safeguarded by ordinary sanitary measures. In this country typhoid fever is essentially a water-borne disease and the majority of us can rely for protection against infection upon the work of our medical officers of health. But the nurse is brought into intimate contact with patients who are suffering from the disease, and those who have had long experience of hospital work will well know that there is in some cases such a thing as personal infectivity in typhoid fever, and that quite apart from careless or unskilful nursing there is a real risk in personal contact. Soldiers living in camp in hot dry climates where typhoid fever is an air-borne as well as a water-borne disease also require special protection. In such a climate it would seem under the prevailing conditions all but impossible to prevent the dissemination to some extent of particles of organic matter from latrines by the wind.

Case.	Sex.	Dilution of serum used in testing for agglutination.			
		1 in 10.	1 in 50.	1 in 100.	1 in 200.

6	F.	,,	—	—	—
7	F.	,,	—	—	—
8	F.	,,	—	—	—
9	M.	,,	—	—	—

Finally, it may be pointed out that whilst the immediate effects of inoculation may be, and often are, decidedly unpleasant they are merely temporary, lasting only for a few hours, and up to the present time have never had any more serious result than the short period of discomfort. It need scarcely be added that if the most ordinary care has been observed in the preparation of the prophylactic fluid there is not the very remotest chance, either in these anti-typhoid inoculations or in the similar procedure against cholera and bubonic plague, of conveying the disease itself. In every case in which it is desired that there should be a prospect of protection lasting for more than two years I think that it is desirable to ensure a good tissue reaction by repeating the anti-typhoid inoculation. The second dose may be given a week after the first, and the agglutinative reaction of the blood tested after a further interval of a few days.

A CONTRIBUTION TO THE STATISTICS OF RHEUMATIC FEVER AND ITS COMPLICATIONS.

BY WILLIAM CECIL BOSANQUET, M.A., M.D. OXON., M.R.C.P. LOND.,

FORMERLY FELLOW OF NEW COLLEGE, OXFORD; ASSISTANT PHYSICIAN TO THE VICTORIA HOSPITAL FOR CHILDREN; MEDICAL REGISTRAR, CHARING-CROSS HOSPITAL.

THE total number of cases of rheumatic fever admitted into Charing-cross Hospital in the course of eight years (1890–97 inclusive) was 450.

Sex and age.—Of the whole number 237 were males and 213 were females, from which it might appear that both sexes are equally liable to the disease. Since, however, there are nearly twice as many male as female beds in the hospital it is probable that these numbers really show a greater liability

of the latter sex to suffer from rheumatism. The following table shows the age-incidence of the cases as admitted to hospital:—

	1 to 10 years.	11 to 20 years.	21 to 30 years.	31 to 40 years.	41 to 50 years.	51 to 60 years.
Males	11	78	79	43	21	5
Females	8	86	82	26	9	2

By far the greater number of cases thus occur between the ages of 10 and 30 years, no less than 157 males and 168 females being included in this period, or over 72 per cent. of the whole number. It is noticeable that within these limits the female cases, in spite of the smaller number of available beds, slightly outnumber those of the other sex. It may be right to point out that the incidence of the disease on children under 11 years may not be fully represented for several reasons. In the first place, the number of children's medical beds in the hospital is only nine and the population from which they are filled is possibly more limited than in the case of adults, owing to the preference of parents for special children's hospitals. Further, it cannot be doubted that the disease often passes unrecognised in children owing to the ill-marked joint-symptoms to which it gives rise at this time of life and the fact that this disease is not popularly associated with childhood. Several instances have come under my own observation in which an illness occurring in a child which was almost undoubtedly rheumatic fever, accompanied by actual swelling of the joints and subsequent valvular disease of the heart, was called "influenza" at the time. In another instance a similar attack was called "malaria"; and it is practically certain that many mild cases of rheumatism which may yet leave serious sequelæ are either entirely overlooked or are treated as mere "feverish attacks," "biliousness," or other creations of household medicine. It might even be suggested that some of the success of salicylate of sodium in the treatment of influenza and some of the cases of cardiac mischief attributed to this protean plague are in reality to be attributed to errors of diagnosis in cases of genuine rheumatism.

Taking first attacks only, including those patients who stated that they had never had a previous attack, and accepting the accounts given by others who were able to fix the date of their first experience of the disease (a total of 304 cases), it appears that no less than 156 (50 per cent.) of these first attacks fell between the ages of 11 and 20 years (females 79, males 77). Under 11 years, 17 cases occurred in male and 21 in female children. From 21 to 30 years there were 42 first attacks in males and 39 in females. The earliest recorded instance among the number was a boy who was reported to have had rheumatism at the age of three weeks. Other early cases were those of a girl aged two years, a boy aged three years (actually observed in hospital), and a girl and boy aged four years respectively. The latest occurrences said to represent first attacks were at 53 and 57 years, both in men. Only one first attack occurred in a woman over 40 years of age.

Heredity.—No very definite reliance can be placed on the family history of these patients, the accounts given of the health of parents and relatives being as a rule untrustworthy, especially with regard to a common and not fatal illness such as rheumatism. As a matter of fact in 99 cases, or approximately 22 per cent., the patients gave a history of rheumatism in one or more members of their families.

Occupation.—With regard to the influence of employment and mode of life only one fact appears at all prominently, namely, the great number of domestic servants who suffer from rheumatism. Out of the present 450 cases no less than 105 (23 per cent.) occurred in this class, 85 being female servants and 20 males. If we add to this number 19 cases of waiters, 10 of barmaids, four of male cooks, and two of office boys, we have a total of 140 cases out of 450, or 31 per cent., belonging to this class of society, while of females alone nearly 40 per cent. were in service.[1] No special liability to rheumatism in those exposed to vicissitudes of weather was evident in this series of cases. The reason for the special incidence on women between 10 and 30 years of age can only be surmised; but the prevalence of anæmia at this period is a very marked coincidence, while both of these diseases seem to fall specially on the servant-class of society. It may be suggested that the existence of anæmia acts as a predisposing cause of acute rheumatism. In this connexion it is interesting to note that in one case, that of a woman, 42 years of age, several attacks had occurred, each in connexion with pregnancy, the period of lactation being always accompanied by rheumatic symptoms. Here, too, perhaps, the anæmia brought about by this drain on the system acted as the predisposing cause. This might well be the case if rheumatic fever is due to the action of some micro-organism, as seems highly probable, although there is little evidence of any transmission of the disease from one individual to another.

Season.—As far as can be gathered from the limited number of cases here recorded rheumatic fever has two periods of maximum incidence in the year corresponding to the months of May and November. That a much larger series is necessary before it is possible to construct a true curve of incidence for the year seems shown by the sudden drop that occurs in the present record between May and June, these months having 47 and 29 cases respectively, or practically the highest and lowest numbers throughout the 12 months (November, the actual maximum, shows 48). It is worthy of remark that while the admissions to this hospital of cases of enteric fever and of acute pneumonia correspond very closely with the accepted periods of maximum frequency of these diseases the cases of rheumatism do not correspond so closely. Probably the seasonal curve of rheumatism is less well defined than that of either of the two other maladies. It is to be remarked that the two months showing the highest averages of cases are months associated, as a rule, with chilly and unsettled weather, when there occur constant changes of temperature.

Onset.—In the vast majority of cases the first thing complained of by the sufferers from rheumatism was pain in one or more joints, which generally began gradually and only caused them to take to bed after one or more days. In a certain number of cases sore-throat was the first thing noticed, apparently in about 5 per cent. Vomiting occurred early in about 3 per cent. of the cases, and shivering or actual rigor in about the same proportion. In approximately 5 per cent. headache was a prominent symptom at the beginning of the illness. Its occurrence later as a result of treatment with salicylates is too well known to need mention and cannot be considered a symptom of the disease.

Another mode of onset, but by no means a common one, was with symptoms of acute pneumonia which masked the pains in the joints, while in one case (that of a girl, aged 14 years) the onset was gradual without joint-pains, but with headache and general malaise, suggesting enteric fever. In another instance enlargement of the spleen was noticed which, if it had occurred along with the former insidious onset, would have caused a misleading resemblance to enteric fever before the occurrence of the typical articular affection.

Duration.—With regard to the duration of the disease it is difficult to say anything definite. When once admitted to hospital the temperature in most cases fell within two or three days, and the pains vanished simultaneously under the influence of salicylate-treatment. On the other hand, patients gave histories of their "rheumatics" having lasted for months before they came for treatment. It is impossible to determine whether these cases are to be considered instances of one long attack or, as seems more probable, as constituting a succession of relapses. Accepting the statements of the patients and calculating from their account of the beginning of their symptoms, the larger number, or nearly two-thirds of the whole, were free from pain and fever within two weeks; but it is impossible to say how long they would have been ill if, on the one hand, they had not come for treatment, or, on the other hand, if they had been treated sooner. Occasionally, even in hospital, cases proved very refractory: in one instance in the present series the patient (a male, 20 years of age) was seven weeks ill in hospital; others were as long as 33 and 39 days, with continued fever and pain in spite of the usual treatment. In two patients, both females, 26 and 36 years old respectively, the disease ultimately settled in one joint and became chronic, the patients leaving the hospital with knees still stiff and painful.

Joints affected.—It is recognised as a feature of the disease that it affects many joints in succession, "flying from one to

[1] The ratio of service to other occupations among 415 female patients admitted during 1898 whose occupations were stated was 26 per cent., which may be taken as the ordinary proportion among patients in this hospital.

another," but on surveying a number of cases it shows a manifest predilection for certain seats. Thus, of about 430 cases in which the affected joints were recorded the knee-joint was affected in 297 instances (69 per cent.), the ankle in 202 (47 per cent.), and the shoulder in 115 (26 per cent.). The elbow, the wrist, and the small joints of the hand and the foot were affected with nearly equal frequency (from 80 to 100 cases); the hip came next with 54 cases and the spine with 37 cases. The neck was affected 11 times, the sterno-clavicular joint eight times, and the temporo-maxillary articulation twice. In 24 cases all the joints were said to be painful, but this vague statement probably only signified the general discomfort and misery of the sufferers. It thus appears that the knee and ankle are nearly twice as often affected as any other joints. The hip-joint, a very frequent seat of rheumatoid arthritis, is not often attacked in rheumatic fever. In a few instances traumatism of a joint (strain, &c.) seems to have determined the seat of onset of the malady.

Complications.—The most frequent complication of acute rheumatism—if it is to be called a complication and not, as seems more probable, a distinct feature of the disease—is undoubtedly endocarditis, and in the present series of cases it was found in 67 males (28 per cent.) and 70 females (33 per cent.) either as recent endocarditis or old valvular disease. In the former sex the mitral valve was affected alone 51 times, the aortic alone in four cases, and both together in 12 instances. In the females the aortic valve suffered alone on two occasions and combined mischief was only met with once, the rest being pure mitral cases. Ulcerative endocarditis occurred in three patients.

Pericarditis was met with in 17 males and 11 females. Of these three died, but in only one of the fatal cases, that of a girl, aged five years, was pericarditis the sole complication, the other two patients having pneumonia, associated in one case with hyperpyrexia. If we add to the above 28 cases of pericarditis 32 others occurring in the hospital in the same period we find that out of a total of 60 cases of this affection 46 (nearly 77 per cent.) occurred in the course of acute rheumatism or were considered "rheumatic." The total mortality of the 60 cases was 19 or nearly 32 per cent., but in four of these the disease was associated with pneumonia, in two with phthisis, and in two with granular kidneys and cirrhosis of the liver respectively. The deaths, therefore, in rheumatic cases, apart from other complications, were nine out of 46 patients, or nearly 20 per cent. On the other hand of 10 cases associated with pneumonia six patients died, or 60 per cent. Two suppurative cases occurred in rheumatic subjects, included in the above numbers, and were both fatal; but they were not associated with symptoms of rheumatic fever at the time of their occurrence. If they were subtracted from the above numbers the mortality of sero-fibrinous pericarditis complicating rheumatic fever would appear to be only about 15 per cent.

The frequency of the occurrence of relapse in cases of rheumatism is difficult to estimate, owing to the fact noticed above that many of the instances of long duration of the illness before admission to hospital are probably due to a series of relapses. Actual instances could be made sure of in 42 cases, or roughly 10 per cent., but the figures are not of much value.

Pneumonia occurred in 14 cases of the present series, equally divided between the two sexes. Of these two, accompanied by pericarditis, were fatal. The total number of cases of pneumonia occurring in the hospital in the period recorded was 300 and in 24 of these—8 per cent—there was more or less reason to associate the disease with rheumatism. It is an interesting speculation to what extent the two diseases are connected, and it is permissible perhaps to surmise that in cases of pneumonia, especially those which run a rather atypical course and end by lysis, closer search would reveal a rheumatic predisposition more often than is at present suspected. In only two of the above 24 cases did the disease end by crisis. The value of salicylate of sodium in acute pneumonia is also of interest in this connexion.

Hyperpyrexia occurred in two cases only, in one of which it was associated with pneumonia. The number seems small, and it is possible that early treatment with salicylates prevents a more frequent occurrence of this fatal complication. Pleurisy was found 14 times and bronchitis in 22 cases; in one patient the latter malady seems to have been responsible for a fatal issue.

Chorea occurred in two males and 11 females, giving an average of nearly 3 per cent. The oldest patients were two girls, 19 years of age. Delirium was noticed in nine cases, chiefly males, several times associated with alcoholic habits, but not always so. In two women there was troublesome neuralgia of the face. Severe abdominal pain was complained of in 13 cases without obvious cause, and diarrhœa occurred in two instances. Four cases presented symptoms of nephritis, two being of the chronic interstitial variety, one a subacute tubal nephritis and one an acute attack; this last occurred in the hospital without any cause that could be discovered other than the rheumatic fever. A purpuric eruption occurred in two cases and hæmaturia in three others, probably due in one case to embolism and in another very possibly to papilloma of the bladder. Epistaxis was twice observed. In one case blood was passed per rectum without obvious cause other than the general disease. Phlebitis occurred once and arterial thrombosis (endarteritis?) affecting the temporal and occipital arteries also in one instance. Of skin-affections, erythema nodosum[2] was observed in nine instances (2 per cent.), all females, and other forms of erythema multiforme in four others (three being women); in two cases it was possibly due to the effect of salicylic treatment. Subcutaneous nodules occurred in five cases, the oldest patient being a woman 26 years of age. In one instance they were the seat of considerable pain. Accidentally associated diseases were gout in six cases (showing that the two diseases are not incompatible), phthisis, Graves's disease, epilepsy, tabes dorsalis, cirrhosis of the liver, and ague.

Death.—In no case of the present series did death occur from an uncomplicated attack of rheumatic fever. Seven cases proved fatal altogether (about 1·5 per cent.), six patients being males and one a female. Two of these cases were due to pneumonia accompanied by pericarditis, one to pericarditis alone: hyperpyrexia accounted for one more. Two cases proved fatal owing to ulcerative endocarditis and one to bronchitis.

Treatment.—With regard to this little need be said. Rest in bed, fluid diet, and salicylate of sodium constituted the routine treatment in all cases. It was often possible to trace a close connexion between the occurrence of a relapse and an unduly early return to fuller diet or a premature omission of the specific drug. In obstinate cases alkalies were tried but did not seem to have much effect. Iodide of potassium, however, occasionally seemed serviceable, aided by blistering of the affected joints in very chronic cases. A recent patient, not included in the above series, appeared to derive benefit from treatment with hot air, a method which is certainly worthy of trial in many cases of chronic joint-disease.

Harley-street, W.

ON OPERATIONS FOR CANCER IN THE AGED.

BY E. HARDING FREELAND, F.R.C.S. ENG.,
SURGEON TO THE ST. GEORGE'S AND ST. JAMES'S DISPENSARY, LONDON.

IN THE LANCET of May 5th, 1900 (p. 1276), there appeared a paper by Mr. T. Frederick Gardner entitled "Three Cases of Surgical Interest." The first of the series—a scirrhous cancer of the breast—raises the question of the advisability of operating for cancer in extreme old age. This case has for me a peculiar interest, as a similar case occurred in my practice about two years ago which, taken in conjunction with Mr. Gardner's case, may be worth recording and prove interesting to others.

A spinster, aged 82 years, thin, wiry, and intelligent, somewhat feeble, but for her years in fairly good health, consulted me on March 18th, 1898, for a painful tumour in the left breast, which, she said, she had noticed about a fortnight previously. She told me that she had been "out of sorts" for several months and she thought that she had been losing flesh. On examination I immediately found a nodular swelling of stony hardness of about the size and shape of a plover's egg in the left breast, situated about an inch below, and external to, the nipple. The skin over the tumour was freely moveable except at one point

[2] The total number of cases of erythema nodosum admitted in the eight years was 20, of which only three were males, aged respectivel 12, 14, and 17 years. The oldest female patient was aged 31 years, th youngest seven years. In the latter the condition was accompanied by glandular enlargement.

where it was dimpled and evidently becoming adherent to the parts beneath while there was a tendency to retraction of the nipple. The tumour was moveable, but not freely so, in the surrounding breast tissue. In the axilla a hard gland as large as an almond was felt under cover of the border of the great pectoral muscle and several smaller shotty glands were apparent higher up. The pain, which was acute and tended to recur in paroxysms, was of a "sharp stabbing" character and was felt not only in the tumour but "down the inner side of the left arm" as far as the elbow. This symptom, which first led the patient to take an anxious view of the situation, was increasing rapidly in severity and was telling considerably on her general health, interfering with sleep and giving rise to much mental distress. Such, then, in brief, is the history of the case to which I wish to call attention.

For reasons which I shall presently state, notwithstanding the patient's feeble state of health and advanced age, I determined to operate and the patient readily consented. Accordingly, on March 23rd, chloroform was administered by my friend Mr. G. Everitt Norton, and I removed in one mass the whole of the left breast, the underlying pectoral fascia, and the axillary glands, together with the whole of the axillary cellular tissue, which was studded with numerous small shot-like nodules. The operation lasted some 40 minutes and was accompanied by considerable shock, from which, however, the patient soon rallied. The wound was dressed for the first time after the operation on the eighth day and union was found to be perfect. The patient was completely relieved of her pain, her appetite returned, she gained flesh, slept well, and became more cheerful. She got up on the fourteenth day and in another week left the nursing home for her own abode. The stiffness in her arm soon disappeared and she was able easily to approximate the palm of the hand to the occiput. Her general health continued good and the patient enjoyed life in her own way without pain or any sign of recurrence to the day of her death, which took place suddenly from heart failure on Oct. 20th, 1899, 19 months after the operation, she having been out for a walk the evening previously. The result, I think, quite justified the procedure resorted to.

"All's well that ends well," says the proverb, and it is easy to shake hands with and congratulate oneself on the success of a perilous venture. In cases such as these the point of prime importance is the accurate gauging of the *pros* and *cons* for operation. In the present instance the patient placed herself unreservedly in my hands, steadfastly refusing to have another opinion, so that on my shoulders fell the responsibility of deciding the momentous question as to whether an operation should be undertaken for her relief or whether she should be left to her fate. On thinking over the case at the time the following questions occurred to my mind: 1. Is it possible to remove the whole of the disease with good prospect of subsequent immunity? 2. Supposing this question to be answered in the affirmative, is the patient in a fit condition to withstand the shock necessarily attendant on a somewhat prolonged surgical operation under anæsthesia? 3. Supposing the two foregoing questions to be answered in the negative, what will be the probable subsequent history of the case if left to run its course? In other words, one had to weigh the risk of shock and risk of recurrence after removal with their attendant consequences against the inevitable increase of the tumour, which would probably sooner or later ulcerate, and the increase of pain which opiates sooner or later would cease to relieve. In the present case the facts seemed to me to be as follows:—1. The complete removal of the disease would entail an extensive operation which would occupy some time and give rise to considerable shock. 2. The patient, though somewhat feeble and advanced in years, was in fairly good health, thin, wiry, and of a cheery, hopeful disposition, and she should be, for her age, possessed of fair rallying powers. 3. The growth was evidently increasing rapidly and the pain was already as much as the patient could bear. On reviewing these facts carefully I came to the conclusion that notwithstanding her advanced years it would be better, on the whole, for the patient to run the risk of operation rather than to face the inevitable and in all probability be condemned to a life of suffering and a miserable death. How far this opinion was justified by the result the brief notes of the case above related bear witness.

No doubt, as Mr. Gardner remarks, cases of scirrhus in people of advanced age are rare. This, I take it, is due partly to the fact that the number of people who reach advanced age, say of 80 years, is comparatively small, and partly that those who do survive to such an age have outlived the time of life at which the incidence of cancer is common. But the chief lesson to be learned from cases such as Mr. Gardner's and my own is, I think, that while we should by no means under-estimate the increased risk which must necessarily occur in operating on the aged we should not without the most mature consideration withhold from a patient, however old, the benefits which surgery alone can bestow.

Beaumont-street, W.

A CASE OF TWO ANEURYSMS OF THE TRANSVERSE ARCH OF THE AORTA.

BY GILBERT J. ARNOLD, F.R.C.S. ENG.

THE following is an account of a case which presents some points of interest.

A patient, a man, aged 40 years, consulted me on March 23rd, 1900, stating that the previous night he had been somewhat alarmed by an attack of difficult breathing. He further stated that he had suffered for some years from bronchitis and emphysema of the lungs and latterly occasional attacks of spasmodic asthma for which he had been under treatment abroad. His voice was hoarse and there was sometimes a dry cough. He had marked inspiratory stridor. The hoarseness had, he said, come on suddenly a few days previously. A laryngoscopic examination revealed the cause of the hoarseness. There was abductor paralysis of the left vocal cord. The larynx was normal in other respects. I should have mentioned that the patient had had, and been under treatment for, syphilis some 16 years ago. A thoracic aneurysm involving the left recurrent laryngeal nerve appeared by far the most probable diagnosis, but an examination of the chest did not reveal any abnormal pulsation, any murmur, any dull area on percussion, or cardiac hypertrophy, neither was there any inequality of pupils or difference in the radial pulses. I did not find tracheal tugging well marked. A guarded prognosis was given and potassium iodide was administered, gentle walking exercise being allowed. A few days later the condition of the vocal cords was practically the same—the right cord moving well and the left relaxed in the cadaveric position; there was therefore some paralysis of adduction too. The hoarseness and inspiratory stridor continued unchanged and he complained of very slight difficulty in swallowing. The dosage of iodide was increased. I by no means anticipated that a fatal termination was so near at hand. On April 16th the patient sent for me on account of slight hæmoptysis. He was put to bed, the services of a nurse were obtained, and the recumbent position was insisted on. Ergot was administered and ice was given to suck. The hæmoptysis, which amounted to half a wine glassful of bright red frothy sputum, ceased within two hours. The patient informed me that he had spat blood on one occasion about three weeks before. He died the next day in bed from a sudden profuse hæmorrhage from the mouth.

Necropsy.—The heart and lungs were practically normal except that the bronchi were partially filled with blood. Arising from the convex upper border of the transverse arch of the aorta was a firm sacculated aneurysm situated between the origins of the innominate and left subclavian arteries and behind the left common carotid, the lumen of which was somewhat flattened out by pressure of the aneurysm. Passing in front and in contact with the sac, which was of the size of a hen's egg, was the left vagus nerve. The sac was nearly filled by firm buff-coloured clot disposed in concentric laminæ. There was a second sacculated aneurysm of the size of a billiard ball also originating from the transverse arch and communicating with it by an aperture of the size of a crown-piece. This sac was in direct contact posteriorly with the trachea and also slightly with the œsophagus, but did not obstruct these structures post mortem, although it probably did so to a slight degree during life when distended by the blood-pressure. It contained recent blood-clot only. On slitting up the trachea posteriorly there was seen opening into it in front the aperture of a small ragged channel of communication, passing between two of its cartilage rings exactly one and a

half inches above its bifurcation, leading into the second sac. Through this channel, which was about five millimetres in length and one in diameter, the hæmorrhage had occurred. On the left side of this sac and intimately incorporated with its adventitious walls the left recurrent laryngeal nerve could be traced, its component strands being spread out and of the same dark colour as the rest of the walls of the sac. From its origin from the vagus under the arch of the aorta until it reached the sac and again above the sac the nerve was of normal appearance macroscopically. It is obvious that its conductivity must have been quite abolished. The arch of the aorta showed gross changes of a chronic inflammatory nature (aortitis). There was great thickening involving all the coats. The thickening was not uniform, but was especially marked in the form of hyperæmic patches, over which the intima was slightly raised. The thickening of the aorta was particularly noticeable around the orifices of the two aneurysms which were distant at their nearest points by about half an inch. Sections here showed marked thickening and hyaline degeneration of the coats; the adventitia and adjacent cellular tissue also exhibited groups of small round inflammatory cells which had penetrated the walls of the aorta. Ordinary atheroma with fatty and calcareous changes was not present in the region of the aneurysms.

The following points about the case may be briefly alluded to. 1. The speedy fatal termination after the onset of the laryngeal paralysis. This symptom had been manifest less than one month. Had the laryngeal paralysis appeared earlier in the case the patient would have heard little of "spasmodic asthma," the dyspnœic attacks being doubtless due to recurrent laryngeal irritation coming on earlier than the paralysis. 2. The narrow channel through which the blood escaped. The aneurysm did not burst. The case closely resembles in this respect the one figured on page 382, vol. vi., of Allbutt's System of Medicine, by Sir W. T. Gairdner. 3. The occurrence of two aneurysms arising so close together in the same vessel—the one having undergone spontaneous cure, the other, probably of much more recent origin, showing no signs of doing so. 4. These aneurysms could not be attributed to strain or laborious occupation. Also, the patient, who was a gentleman, had, as far as I could learn, never indulged in much exercise and for some years had regarded himself as rather an invalid. He was of temperate habits, but he certainly had had syphilis years ago and most probably the lesions in the aorta (arteritis) have an etiological connexion with that fact.

INTESTINAL OBSTRUCTION DUE TO PERSISTENT MECKEL'S DIVERTICULUM; SUCCESSFUL LAPAROTOMY.

BY F. FAWSSETT, M.B. LOND.,
SURGEON TO THE LEWES INFIRMARY AND VICTORIA HOSPITAL;
AND
R. F. JOWERS, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE SUSSEX COUNTY HOSPITAL.

A HEALTHY girl, aged 11 years, went to bed in her usual health on the evening of March 13th, 1899. Although her bowels had been twice relieved during the day she was given a dose of compound liquorice powder. At midnight she awoke with violent pain in the abdomen and was sick several times. On the following day, March 14th, she was seen by Dr. Fawssett, who prescribed an effervescing mixture containing diluted hydrocyanic acid, iced milk, and soda-water, and also hot fomentations to her abdomen. The pain was a good deal relieved but recurred at intervals. Vomiting occurred, but only after taking nourishment, and two or three times the milk-and-soda was retained. No action of the bowels took place. On March 15th no food was given by the mouth and vomiting only occurred once, when the child was moved in bed. As the pain continued and as nothing passed per rectum Dr. Fawssett held a consultation with Dr. R. Sanderson late in the evening of this day. An enema of warm water was given which returned clear with the exception that the last portion was slightly blood-stained. While the water was retained it was thought that an indistinct lump could be felt in the right iliac region. Much gurgling and peristalsis were present. The diagnosis arrived at was acute intestinal obstruction, probably due to intussusception. A small dose of morphia was given hypodermically. As it was then late and as the patient was at Lewes it was decided that Mr. Jowers should be asked to operate in the morning.

On March 16th, at 11 A.M., Mr. Jowers saw the patient with Dr. Fawssett. The child complained of pain at the umbilicus, the abdomen was hard and rigid and slightly distended, distended coils of intestine could be seen, and there were marked peristalsis and gurgling on pressure. No lump could be felt. The tenderness seemed more marked in the left iliac region than elsewhere, the rectum was empty, and no motion or flatus had passed. The child was slightly under the influence of morphia at this time. Dr. W. A. Dow gave chloroform. The abdomen was opened below the umbilicus. On dividing the peritoneum a quantity of serous fluid escaped, greatly distended small intestine bulged into the wound, and after a considerable quantity had been drawn out of the abdomen and covered up in warm boiled towels, a bunch, consisting of several coils of collapsed small intestine, was found tightly nipped by a thin cord which came from the extremity of a Meckel's diverticulum, which was again attached to bowel, forming a ring through which the strangulated coils had slipped. The bowel down to, and including, the diverticulum was greatly distended. The patent portion of the diverticulum was about one and a half inches long and its base or opening into the bowel was fully two inches. To have excised it would have prolonged the operation, but as it was found to be impossible to return the bowels in their distended condition it was determined to utilise the diverticulum to relieve the distension. After covering the wound and the bowels, with the exception of the diverticulum, with boiled towels, the extreme tip was cut off with scissors, making a small opening through which a quantity of gas and a small quantity of liquid fæcal matter escaped. The mucous membrane, which slightly prolapsed, was ligatured and returned, and the peritoneum was then sutured by a double row of Lembert's sutures so as to invert and considerably shorten the length of the diverticulum. The abdominal wound was closed with silkworm-gut sutures, a glass tube being inserted for 24 hours. On the following day the tube was removed and the opening left was closed by a suture introduced for the purpose at the time of operation. Recovery was uninterrupted, there being no sickness and the temperature not rising above normal. The sutures were removed on the tenth day.

The striking thing about this case was that, considering the tightness of the constricting band, the symptoms were not more severe. The vomiting was never stercoraceous or continuous, the child did not look seriously ill, and the temperature was below 100° F. On the day preceding operation she vomited only once. Nor was this absence of vomiting due to masking of symptoms by morphia, as none was given till the night preceding operation.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON THE PASSAGE OF A CALCULUS OF EXCEPTIONAL SIZE THROUGH THE RIGHT URETER AND THE URETHRA OF A MAN ABOUT 50 YEARS OF AGE.

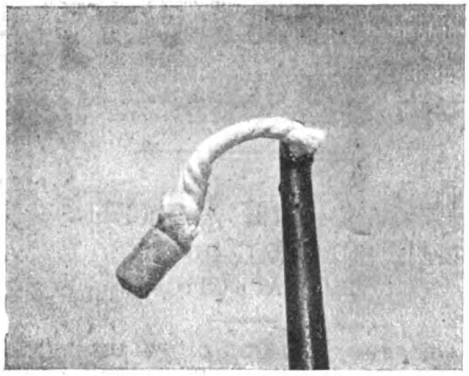
BY J. A. CUNNINGHAM, M.D., M.CH., R.U.I.,
MAJOR, I.M.S.

THE appended illustrations are faithful representations of a calculus composed chiefly of oxalate of lime with a coating in spots of urates and phosphates, which was passed recently by an officer in the Punjab Public Works Department. In its longest diameter the calculus measures fully half an inch.

It is of an irregular oval shape with nodular projections, and when quite dry it weighed seven grains.

The attack of renal colic began when the patient was out in camp towards the end of January, 1900, and when he was at a distance from medical aid. When the attack had lasted

Three different views of the calculus. Actual size.



10 days without relief and the patient was nearly exhausted he was visited by a medical officer from a neighbouring district who advised him to proceed to Delhi, where it was expected that an operation would be required to relieve him. He undertook the journey (about four hours by rail and with accommodation for lying down) with some apprehension, but except that he felt weak and exhausted it did him no harm. On arrival it was found that the paroxysms of pain had ceased, and he was conscious that the calculus had reached his bladder, having taken 11 days to pass through the ureter. The pain was not constant during this period, but it occurred in intermittent paroxysms lasting from five to 20 hours each time. After remaining for seven days in the bladder the calculus was voided with the urine without much inconvenience.

Delhi.

REMOVAL OF A FOREIGN BODY FROM THE EAR.

BY JAMES G. MACASKIE, L.R.C.P., L.R.C.S., D.P.H. EDIN.

I WAS called in to see a schoolboy who had pushed into the right meatus a piece of indiarubber which had previously been attached to a lead pencil. I found that he had driven the rubber well in, and as it was almost an exact mould and presented to view an entirely flat surface it was impossible to catch it with forceps and syringing did not seem likely to improve matters. I therefore, on the following day, teased out the end of a small piece of twine and giving this a good coating of seccotine I pushed it tightly against the india-rubber, packing it closely all round with cotton-wool. This was allowed to remain in position for 24 hours when there

Reproduction of photograph of indiarubber and string attached. Actual size.

was firm cohesion and I found not the slightest difficulty in withdrawing everything *en masse*. I may mention that before forming the connexion I thoroughly cleaned away all the wax, of which there was a good deal, with ether. It is very possible that this expedient is by no means new, but as it was so successful I beg to suggest it to any who may be confronted with the same difficulty.

NEW HOSPITAL FOR WOMEN.

THREE CASES OF INTESTINAL SUTURE.

(Under the care of Mrs. STANLEY BOYD, M.D. Brux.)

THE three cases recorded below illustrate well two of the more important conditions for which intestinal suture may be required. Cases 1 and 3 are examples of short-circuiting for irremoveable malignant disease, and Case 2 is a good instance of resection for gangrene and adhesions. Post-operative intestinal obstruction is yearly becoming more frequent, for abdominal operations are now much more readily undertaken than was even lately the case. It is probable that complete covering of the pedicles of ovarian tumours by peritoneal flaps would diminish greatly the tendency to the formation of post-operative bands.

CASE 1. *Ileo-colostomy for intestinal obstruction due to malignant growth involving the iliac glands and cæcum.*—A married woman, aged 27 years, was admitted to the New Hospital for Women on June 30th, 1897. Vaginal hysterectomy had been performed in August, 1896, for malignant disease of the cervix uteri. It was an early and favourable case and she recovered well, leaving the hospital between two and three weeks after operation. In January, 1897, she attended as an out-patient, complaining of flatulence which was relieved by ordinary medical treatment. Nothing further was heard of her till the next June when she wrote complaining of flatulence. On June 30th she attended at the hospital and was admitted. She gave the following history. The bowels had acted regularly up to June 7th. On that day she was seized with violent pain in the abdomen and vomiting which lasted a few hours and recurred four days later after taking some castor oil. The bowels did not act until the 15th (one week's constipation), when the action gave great relief. From that date, in spite of salts, liquorice powder, and enemata, she had had no real relief, although an enema had occasionally brought away small scybala. Flatus was passed only once or twice without an enema. She had suffered much from colicky pain and nausea. She had taken only liquid food. Her face was anxious; the pulse was 120, falling when she was in bed to 88. The vaginal scar was quite soft and normal. The abdomen was hard and tense and distended coils of intestine and peristaltic movements were visible. It was thought that probably a coil of intestine was kinked by adhesion to the vaginal scar and that by carefully given enemata it might be possible to unload the bowel and relieve her for the present. She was ordered regular enemata and gentle massage of the abdomen. She remained in much the same state till July 4th. The enemata had practically no result, nor had some small doses of castor oil repeated at six hours' intervals. On the 4th she felt sick towards evening and during the night. It was therefore decided to open the abdomen.

An operation was performed on July 5th. On opening the abdomen by a median incision above the pubes distended small bowel presented. The source of obstruction was found to lie in a mass of malignant glands lying along and adherent to the right external iliac vessels, infiltrating and binding down the cæcum; to this was adherent also by infiltration of its wall with growth the lower end of the ileum. The ascending and transverse colon beyond the obstruction were contracted and pale. In separating a coil of distended ileum which hung down into the pelvis and was firmly adherent there its peritoneal coat was slightly torn. As complete removal of the malignant mass was impossible it was decided to short-circuit the bowel. The transverse colon was drawn down after ligature and division of omental

adhesions which held its left end. A convenient coil of ileum was selected to attach to it, but in the preparatory packing round of sponges the coil which had been adherent in the pelvis was torn where it had been injured by separation of adhesions. It now seemed best to utilise this tear, as the injured coil could be brought up to the transverse colon without much difficulty. Liquid fæces had escaped as the bowel tore, but the escape was promptly arrested. The bowel was then brought outside the abdomen, allowed to empty itself, and cleansed with 1 in 2000 solution of perchloride of mercury. It was then clamped above and below the tear by an assistant's fingers. At first peristalsis was strong and forced out gas and even a little fæces. The tear was larger than was desirable and was transverse and therefore a little more difficult to bring into line with a longitudinal incision in the colon. Longitudinal traction rendered it diamond-shaped and its lower edge was attached along the length of the transverse colon by two rows of horsehair sutures; the first row, a glover's suture, took up the peritoneum and the muscular coat, while the second row consisted of three interrupted sutures in the centre and at either end, a continuous suture which was carried (after longitudinal incisions of the transverse colon) round the angles to form the deep row in front of the opening. A second anterior row of Lembert's sutures completed the union. The deep row of sutures surrounding the openings into the bowel was thus completely buried. The parts affected were then carefully cleansed with a lotion of perchloride of mercury (1 in 2000), the bowel was returned, the peritoneum was sponged out, and the abdomen was closed by tier suture without drainage. The pulse at the end of the operation was 132 and very compressible. A hypodermic injection of a quarter of a grain of morphia was given to check peristalsis. The patient was fed by nutrient enemata.

On the day after the operation flatus was passed per rectum and on the 8th (three days after the operation) the patient passed a normal motion without pain or blood. From this time she was fed by the mouth and the bowels acted well; sometimes mucus was passed with the stool and sometimes the bowels were loose, but on the whole there was no trouble. On the 10th the abdominal wound was found to be suppurating and required to be opened up freely. She was discharged from the hospital on August 12th with the abdominal wound nearly healed. It was noted that the mass in the iliac region had not increased. On August 18th a thickening was felt per vaginam in the left fornix. On Sept. 12th information was received that a vaginal fæcal fistula had developed and that the patient was suffering much from flatulence. The abdominal wound had healed. On Sept. 20th pus had made its way through the abdominal wound. On Dec. 1st she was seen. She was keeping her bed; the vaginal fæcal fistula had closed. There were two sinuses in the lower part of the abdominal wound; to the right of the scar a hard mass extended out into the right iliac region. It was not clear whether this abscess was in direct continuity with the earlier suppuration in the abdominal wound, burrowing towards the vagina as the abdominal sinus closed and later reopening this track, or whether it formed independently round about the diseased bowel and glands, making its way to the surface by the easy route of the abdominal and vaginal scars. The patient died in March, 1898, from gradually increasing weakness without any recurrence of obstruction.

CASE 2. *Resection of the small intestine for gangrene from obstruction by band.*—A young woman, aged 23 years, unmarried, underwent abdominal section in the new Hospital for Women on Dec. 31st, 1897, for the removal of a large multilocular cyst of the right ovary which filled the abdomen up to the liver; there were no adhesions. The contents of the cysts were so thick that the trocar was useless; the opening had to be enlarged and the cysts broken down by hand; some of the contents, in spite of careful packing, escaped into the peritoneal cavity. Otherwise the operation was easy and convalescence was uninterrupted, the wound healed by first intention, though the evening temperature was usually above 99° F. After three weeks she was sent to the convalescent home, and before she left it was noted that the uterus was freely moveable and in normal position and that the rectum was slightly ballooned. The bowels were opened on Jan. 20th, 1898, the day before she left the hospital. On the evening of the 23rd, after an indigestible supper of mince-pies and nuts, which the patient managed to procure, she had severe abdominal pain and vomiting, the vomiting continuing for two days. She took an aperient, the bowels not having been opened since the 20th, but it acted hardly at all. On the 25th an enema was given without effect and some milk with brandy was given by the mouth; this the patient retained. She was brought back to the hospital on the same afternoon. On admission the temperature was 100·8°, but after this it did not rise above 99·6° or the pulse over 100. There was little to note; the abdomen was not distended, the patient seemed to be fairly comfortable, and when fed frequently with small quantities retained her nourishment. Enemata were given and acted. On the night of the 26th she vomited jelly-like mucus and some brown stuff which was said to have had a fæcal odour. There was no further vomiting for 36 hours, but on the morning of the 28th her aspect had changed for the worse. She was complaining more of pain, chiefly over the stomach, and it was paroxysmal in character. The enema given had acted only very slightly. The abdomen was somewhat distended and moved with respiration, but a transverse coil of intestine was visible. There were signs of a small amount of fluid in the abdomen. The pulse remained about the same, 96, and fairly good. The tongue was red and fissured, but not dry. At noon the patient vomited a large quantity of "fæcal" fluid and operation was undertaken without further delay.

The abdomen was opened through the former scar without any parietal adhesions being encountered. Dilated and congested small intestine presented. The hand, passed behind the uterus, found it and Douglas's pouch to be free from adhesions. The pedicle of the former cyst was adherent to the right pelvic wall and from the back of it passed upwards two or three tense bands which bound down certain coils of intestine. A small amount of blood-stained fluid was found in the abdominal cavity. Two coils of intestine were adherent to each other and these were brought up, dissected free, and bleeding points tied. The intestine so freed was followed up and was found to be held by one of the above-mentioned bands which was ligatured and divided. The bowel above the band was considerably dilated and that below was completely collapsed and it had sloughed just where the band constricted it. About eight inches along the collapsed bowel was a sharp kink caused by dense adhesion to each other of the walls of a short loop of intestine—adhesion so dense that it would obviously have been almost impossible to dissect them apart without lacerating the bowel. It was therefore decided to resect the whole piece up to and including the gangrenous line of stricture. About eight inches were thus cut away, the vessels of the mesentery being secured as they were divided. The cut ends of intestine were brought together by a Murphy's button, but the distal end was so collapsed that it was not easy to introduce the button here, and the bowel was quite markedly stretched over it. On pushing the button home the mucous membrane of the dilated upper end bulged out and had to be trimmed off. A continuous Lembert horsehair suture was applied all round and the V-shaped wound in the mesentery was closed by interrupted horse-hair sutures. The coil of intestine was then sponged with saline solution and dropped back into the abdomen. Two omental bands and the sigmoid flexure were freed from the back of the pedicle. The peritoneal cavity was sponged out and the abdomen was closed by tier suture. A saline injection was given while the patient was still on the table.

The pulse at the end of the operation was 120 and by the evening 130 and the temperature rose to 104°. Flatus passed freely once and on Jan. 30th the bowels acted twice after an enema, the stools being very offensive. There was no blood in the stools. Abdominal pain was a marked symptom for the first few days. Feeding by the mouth was begun on the 30th. By Feb. 1st the temperature had become normal and on the 4th the wound was found to be healed. After this there was a check; vomiting returned with increase of pulse and temperature, and by Feb. 15th an induration had formed to the right of the scar and necessitated re-opening the abdominal wound. A localised collection of pus was found deep to the muscle and pressure on the right iliac fossa caused fresh pus and a very small quantity of fæcal matter to well up. A probe passed in did not strike the button. The cavity was drained by iodoform gauze, the temperature fell, the discharge lost all fæcal admixture, and the sinus closed on April 13th. The button was passed on Feb. 17th, the twentieth day after the operation. Throughout the convalescence aperients were needed and there was always a certain

amount of distension of the abdomen. The patient returned to her work and went on fairly well until September, when she had an attack of abdominal pain and sickness with three days' constipation relieved by castor-oil. During the next five weeks she was sick on four occasions and brought up blood and had attacks of constipation lasting from three to seven days. As self-administered enemata failed to overcome the constipation and the retching and pain continued, she was re-admitted to the hospital on Nov. 1st. The abdomen was a good deal distended on admission and the temperature was slightly raised, being 99° or 100°. For a fortnight she was dieted and treated with enemata and purgatives with varying result. Occasionally there was a good action, but the distension was little relieved and it seemed clear that she was suffering from some chronic obstruction.

On Nov. 19th the abdomen was re-opened through the upper end of the old scar. There were no adhesions of omentum or bowel. A large portion of small intestine was found collapsed. A fibrous band three inches long uniting two coils of bowel was tied at both ends and cut. A second fibrous band was found and from beneath this a large mass of collapsed small intestine was withdrawn. This fibrous band was found to take origin from a coil of small intestine close to the site of the former resection, which was marked by a slight but distinct constriction. Here, in the bowel and in the mesentery, horsehair stitches were embedded, while from the free margin of the bowel projected about two and a half inches of horsehair surrounded by a fibrous envelope, evidently part of the continuous suture inserted to reinforce the button. The strictured coil lay in the pelvis. The horsehair knots and stitches were cut out and the peritoneal coat reunited with fine interrupted sutures of catgut. No other bands were found and the abdomen was closed by tier suture without drainage.

The patient made an excellent recovery with much less pain than on the previous occasion and the bowels acted after an enema on the fourth day. She was discharged from the hospital on Dec. 12th with the wound soundly healed and the bowels acting regularly with the help of mild aperients. She has remained well up to the present time, although she always has to take aperients and gets at times attacks of vomiting, when she is said to bring up blood. This, however, was not substantiated when she was again admitted to the hospital for observation after such a reported attack. During each convalescence there was evidence of the patient's hysterical tendencies.

CASE 3. *Gastro-enterostomy for malignant disease of the stomach and pancreas.*—A married woman, aged 37 years, was admitted to the New Hospital for Women in November, 1898, under the care of Miss Cock, M.D. Brux. There was a history of nine months' definite illness and of an attack of vomiting 15 months previously which passed off. For nine months the patient had noticed a small lump in the epigastric region to the right of the mid-line and had suffered from abdominal pain, discomfort, and distension. These attacks of pain were terminated and relieved by vomiting of large quantities of offensive liquid. At first the attacks occurred with weekly intervals, but later the intervals were only from 24 to 48 hours, and the pain had become more or less continuous. She had never vomited blood. In August, 1898, her weight was 6 st. 4 lb. On admission it was 5 st. 4 lb. There was no history of previous gastric trouble or of syphilis. On admission it was noted during an attack of distension that there was considerable separation of the recti. The upper part, sometimes the whole abdomen, was distended by the stomach. The outline of the smaller and greater curvatures could at times be distinctly seen as well as felt. They extended respectively to the level of the umbilicus or just above it (smaller curvature) and to the pubes (greater curvature). On palpation succussion splash and waves of peristalsis could easily be obtained over the dilated stomach, and to the right of the mid-line just below the liver and beneath the edge of the right rectus muscle a tumour of the size of a small egg could be plainly felt, hard, not tender, moveable both vertically and laterally, separable from the liver edge. The vomit which was offensive and chiefly fluid, contained neither blood nor sarcinæ. As much as three or four pints were brought up at once. The patient remained in the hospital over three weeks and at first derived slight benefit from medical treatment and dieting; the improvement was not maintained, however, and after leaving the hospital the symptoms were as bad as ever. Her weight on her discharge was 4 st. 8 lb. On March 17th, 1899, she was re-admitted to a surgical ward with a view to operative measures. Her weight on admission was 6 st. 2 lb., a distinct gain in spite of the persistence of the symptoms. The local condition was unchanged except that the distension was more intermittent. The patient was most anxious for surgical relief.

After preliminary washing out of the stomach for four days, and immediately before operation, an exploratory laparotomy was performed on March 23rd. The incision, which was three inches long, extended to within an inch of the umbilicus and part of the anterior wall of the stomach presented in the wound. Examination showed the tumour noted above to be an infiltration of the coats of the stomach near the pyloric end, involving and constricting the whole circumference and welding it into one mass with the similarly infiltrated pancreas below. The pyloric orifice as apart from the mass could not be made out nor could the foramen of Winslow be traced. There were hard glands in both omenta. The liver was unaffected. As the infiltration of the pancreas rendered an excision of what was regarded as a malignant growth impossible gastro-enterostomy was resolved upon. The most dependent part of the stomach was drawn upwards out of the wound and the posterior wall of the stomach was exposed by a crucial incision through the transverse mesocolon. The commencement of the jejunum was felt for and a high coil that would lie in easy proximity to the stomach was selected and clamped, gauze veils being carefully packed round and beneath the stomach and intestinal coil. The viscera being held in contact two rows of continuous Lembert's sutures of fine silk were passed over a length of two inches and tied. An anterior row of interrupted stitches was passed, leaving sufficient space for opening the viscera between this row and the two previous ones; these were not tied, their ends being left long, clamped, drawn aside, and protected, while the viscera were opened for some one and a half inches. Small bleeding points were secured. The surfaces having been well sponged with saline solution the mucous coats were brought together with a few interrupted silk sutures to keep them out of the way, and the anterior row of sutures was tied and reinforced by a second row of continuous silk sutures anterior to them. The parts were again well sponged with saline solution and returned to the peritoneal cavity, where they lay without strain, the transverse colon falling naturally into position in front of them. The abdominal wound was sutured in layers.

The patient made an excellent recovery. She was fed by nutrient enemata for two days but from the first was given sips of hot water by the mouth. On the third day milk was given by the mouth in teaspoonfuls, and by the sixth day all rectal feeding was stopped and she was given minced meat by the mouth. There was no sickness from the time of the operation and there was no pain. She was discharged from the hospital on April 8th feeling better than she had felt for months. Her weight on discharge was 6 st. 2 lb. Owing to the tension of the recti from the line of suture it was no longer possible to make out the swelling in the neighbourhood of the pylorus, but the shape of the abdomen had become much more uniform and the rather marked distension which at first existed in the neighbourhood of the wound had quite disappeared. The patient was seen on Nov. 1st, 1899, her weight then being 7 st. 8 lb. She expressed herself as being extremely well. She was able to do all her own work and had gained flesh and colour in a remarkable way. The tension of the recti was still so marked as to preclude the possibility of feeling the tumour, the abdomen was uniform and symmetrical, but perhaps slightly fuller above than below the umbilicus. To percussion the greater curvature lay at the lower limit of the abdominal scar (about one inch above the umbilicus). In March, 1900, her weight was 7 st. 12 lb. and her health continued excellent. The epigastrium was less tense and palpation was possible. Nothing could be felt of the tumour which seemed to have diminished or disappeared.

Remarks by Mrs. BOYD.—In Case 2 the second operation gave an opportunity of observing the nature of the junction effected by Murphy's button. It cannot be considered a typical case on account of the reinforcing line of suture, and further the intra-peritoneal abscess that formed after the first operation was undoubtedly due to leaking at the site of the button. The difficulty in adjusting the button to ends of such different calibre was answerable for this, causing at the

proximal end considerable frilling of the mucous membrane, and at the distal end dangerous pressure from distension by the button. The line of suture was not efficacious in ultimately preventing leaking, although it was doubtless useful in strengthening the junction until adhesions had formed round about. The late development of the abscess points to this conclusion, although the early abdominal pain suggests irritation about the line of junction. That the continuous stitch had cut out at some time was clear from the length of straight horsehair found hanging from the free margin of the bowel, while the mesenteric portion remained embedded with no sign of irritation. This would seem to point to certain disadvantages in the use of a somewhat rigid, non-absorbable suture for a continuous stitch where it happens to cut out, for the long end thus found surrounded by organised lymph might certainly have proved an additional trap for the bowel. The external stricture at the line of junction was extremely slight and there was no marked thickening to suggest that the calibre of the bowel might be diminished disproportionately. It is interesting to note the very slight evidence that remained at the second operation (after an interval of six months) of the fairly extensive intra-peritoneal abscess—viz., the two distinct fibrous bands passing from one part of the intestine to the other. Indeed, it is not clear that these bands may not have had their origin after the ovariotomy with the band that formed the first source of obstruction, but were overlooked as causing no trouble at that time.

Case 3 calls for little remark except to emphasise the extremely easy convalescence with entire absence of pain and intestinal worry. This seems partly due to the area of stomach chosen for anastomosis, allowing the viscus to lie after suture in a perfectly natural position. The ease of access and the convenience for suture were equally marked. The disappearance of the tumour and the prolonged improvement in the patient's health make it probable that the obstruction was cicatricial rather than malignant, as was diagnosed at the time of operation.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Exhibition of Cases and Specimens.—Annual Meeting.

A MEETING of this society was held on May 29th, Mr. A. PEARCE GOULD being in the chair.

Dr. MORLEY FLETCHER exhibited a specimen of Hypertrophied Brain which had been removed from the body of a boy, aged 10 years. During life the head was noticed to be of unusual size. The child was somewhat backward but not imbecile. The father had rather a big head. The skull-cap and membranes were normal, the weight of the brain being 73 ounces. There was a uniform increase in size and the different parts were also all relatively increased. Microscopically the chief change consisted of an increase in the neuroglia. In various parts were found non-nucleated round bodies, more abundant in the white matter. They were dissolved by xylol and probably consisted of some fatty substance. This was the heaviest brain on record as far as he (Dr. Morley Fletcher) was aware and corresponded to the pathological variety known as cerebral hypertrophy. The recorded cases had been found in children and adults, most of whom exhibited a deficiency of intellect. Megalencephalic would be a more suitable name. He was indebted to Sir Dyce Duckworth for permission to publish the case.

Dr. FLETCHER also exhibited a Tumour of the Posterior Mediastinum probably originating in the sympathetic system. The patient was a woman, aged 32 years, who was admitted under the care of Dr. P. J. Hensley into St. Bartholomew's Hospital. She had had pain in both groins and later pains in the chest and all the symptoms of mediastinal tumour. There was excess of white corpuscles in the blood. A small nodule of secondary growth was present in one lung. The tumour measured six inches vertically and consisted of two lobes. The tumour had also invaded the spinal canal though not the intra-dural cavity. Microscopically the tumour consisted of myxomatous tissue with fibres resembling non-medullated nerve fibres and cells resembling sympathetic nerve cells. Other parts of the tumour were sarcomatous with spindle cells. In the spinal canal the structure was different. It was suggested that the tumour originated in a sympathetic ganglion and that it was a neuroma.—Dr. H D. ROLLESTON, remarking on the rarity and interest of the growth, suggested that it should be referred to the Morbid Growths Committee and this suggestion was adopted.

Dr. MORLEY FLETCHER and Mr. H. J. WARING exhibited two cases of Congenital Sacro-coccygeal Tumour. The first was removed from a child, aged two years, who was under the care of Mr. J. Langton at St. Bartholomew's Hospital. The tumour which was present at birth had been gradually increasing in size. It was removed, but two months later the child returned with recurrence in the iliac and lumbar glands. The primary tumour and the pelvis were both exhibited. The tumour was cystic, the cysts being lined by columnar epithelium. The more solid portions had the structure of an adeno-carcinoma. As far as Dr. Fletcher and Mr. Waring knew no other case had been recorded of a congenital sacro-coccygeal tumour becoming carcinomatous. The second specimen shown was a sacro-coccygeal tumour from an infant, seven days old. This was a cystic tumour containing spindle and round cells, myxomatous tissue, and cartilage. The embryological origin of these forms of congenital tumour was discussed.

Dr. E. CAUTLEY showed the brain from a case of Congenital Hydrocephalus with Complete Atrophy or Non-development of the Prosencephalon. The patient was a male infant, aged four months, who died after an illness of three weeks' duration, characterised by vomiting, drowsiness, occasional screaming, spastic rigidity of the limbs, retraction of the head and rigidity of the neck muscles, exaggeration of the knee-jerks, and extensive craniotabes. The head was of normal size for the age and weight of the child, but the sutures and fontanelles were open, the anterior fontanelle being large and bulging. The brain was represented by the medulla oblongata, pons varolii, cerebellum, crura cerebri, and optic thalami, all of which were small and ill-developed. The rest of the brain consisted of a membranous bag composed of two dilated lateral ventricles, which had held about a pint of clear watery fluid. The membrane was about the same thickness as the dura mater in a normal adult and did not appear to contain any nervous tissue elements. Dr. Cautley ascribed the condition to an excessive formation of fluid in that part of the anterior cerebral vesicle known as the prosencephalon or procerebrum, and interference with its escape. This probably occurred very early in fœtal life and the prosencephalon became a membranous bag containing fluid instead of developing into the usual cerebral hemispheres, lateral ventricles, corpora striata, and olfactory lobes.

Mr. WALTER EDMUNDS exhibited the Thyroid of the Puppy of a Bitch from whom the Thyroid had been Removed. Halsted had shown that the thyroid of a puppy from a bitch partially deprived of its thyroid was hypertrophied; it was about 20 times larger, and microscopically the colloid was absent and the vesicles were very rare. This experiment Mr. Edmunds had repeated. Nearly the whole of the thyroid was removed from a bitch, leaving only one parathyroid and a morsel of thyroid proper. A few months later the bitch gave birth to a puppy and it was found that the thyroid of the puppy was large. Microscopically the colloid was absent and the secreting cells lining the vesicles were hypertrophied. These were the appearances of compensatory hypertrophy. It had been observed that the health of women suffering from either myxœdema or Graves's disease was much improved by pregnancy.

Dr. ARTHUR SAUNDERS exhibited the Legs of a Duck which had Webless Feet. He had only been able to find records of two instances of webless feet in ducks, one by F. O. Morris in *The Zoologist*, vol. iv. (1846), p. 1214, and one by Möbius in the Transactions of the Zoological Society of Frankfort-on-Maine, vol. xviii. (1877), p. 223. It was a congenital deformity. There was no abnormality in the duck excepting the absence of the web, which was represented by a slight membrane. The duck was able to swim, but not so well as other ducks.

Mr. S. G. SHATTOCK exhibited some Anatomical Rarities: 1. The hand and forearm of a chimpanzee in which the tendons of the flexor profundus digitorum were ruptured near their insertions into the terminal phalanges. The tendon of the index was tied in a knot around the unruptured tendon of the flexor sublimis after having been

completely withdrawn through the perforation in the latter. The rupture doubtless arose from a violent contraction of the muscle made to save a fall, whilst the terminal phalanges of one hand alone supported the weight of the body. 2. Unilateral synostosis of the temporo-maxillary articulation, preceded by an unusual amount of destruction of the jaw. No history was forthcoming. The degree of destruction suggested a tabetic arthropathy. The whole of the condyle and neck, with a portion of the ramus, had completely disappeared. 3. The tusk of an African elephant presenting a sharp angular curvature. Its surface showed the results of superficial destruction, associated with abnormal productions of cement, indicative of an alveolar periostitis. These changes explained the occurrence of the curvature. In consequence of a condition like that of pyorrhœa alveolaris in the human subject the tusk became loosened and by its sheer weight then underwent downward displacement. As the production of ivory proceeded from the persistent pulp in the base the deeper or growing end of the tusk formed—i.e., after the occurrence of the displacement had been developed in the normal axis. Mr. Snattock questioned whether the mobility of the tusk of the elephant, usually regarded as normal, was not really a result of alveolar inflammation, for such observations related to animals living in the unnatural conditions of captivity. In man pyorrhœa alveolaris was known not only to induce premature absorption of the alveoli and exposure of the fangs of the teeth, but in extreme cases a tooth isolated by this disease might assume a horizontal position; were it furnished with a persistent pulp the after-growth would be followed by a curvature, as in the case of the tusk described. 4. Two Umbilical Calculi which consisted of squamous cells and hairs with needles of fatty acids. They had been removed from the umbilicus, in which situation they had produced a suppurative sinus.

Dr. JOHN FAWCETT exhibited a Fibroid Lung following Broncho-pneumonia. The patient, a child, had been admitted several times into Guy's Hospital under the care of Dr. Hale White with recurrent bronchitis and broncho-pneumonia. At the necropsy both lungs were found to be affected with old and recent pleurisy, thickening of the pleura, and a general increase of the fibrous tissue. As to the etiology of the condition broncho-pneumonia was the cause in this case, as it generally was in children. In looking up the Guy's Hospital post-mortem records from 1875–98 inclusive Dr. Fawcett had found that there had been 97 necropsies on cases of fibroid lung apart from tuberculous disease. In 43 of these the exciting cause was apparently some pleural lesion and in only five of these could there be said to have been any acute pulmonary lesion which might have been a "pneumonia." 18 of the cases were thought to be syphilitic and 10 were due to broncho-pneumonia. The majority—viz., 57—of the Guy's Hospital cases were between 30 and 60 years of age. These data were quoted to show that when a larger number of cases were taken it was clear that fibroid lung affected a longer period of life than was stated by some observers and also to show that pleurisy might be in later years probably quite as potent a factor in the causation of fibroid lung as broncho-pneumonia in the earlier ones.

Dr. A. J. CLEVELAND and Dr. J. FAWCETT exhibited a specimen of Diplococcus from a case of cerebro-spinal meningitis. The patient was a youth, aged 19 years, who died after an illness of five days. At the necropsy there was turbid serum in the ventricles and round the spinal cord. In the lymph at the base of the brain and round the cord diplococci were found, but no cultures could be obtained from this or from the serum or from the blood.

Dr. H. D. ROLLESTON showed a Pedunculated Spindle-celled Sarcoma arising from the submucous coat of the posterior surface of the œsophagus in its middle third. The tumour was white, friable, and in places superficially ulcerated. The base of attachment measured three inches on the long axis of the gullet. The growth was moulded to fit the lumen of the œsophagus and therefore was more pedunculated in the long than in the transverse axis of the gullet. It extended from a point one inch above the cardia to within one and a half inches of the cricoid. Reference was made to seven other recorded specimens, of which three—Targett's, C. Ogle's, and Livongood's—were pedunculated. Most of the cases were spindle-celled and arose from the submucous coat. Clinically, sarcoma resembled carcinoma of the œsophagus. The specimen was from a man, aged 49 years, who died with œsophageal obstruction.

Dr. FRANCES H. HAWKINS exhibited as a card specimen a Lympho-sarcoma of the Thorax occurring in a child, aged six years.

The annual meeting of the society was held subsequently. The report of the council showed that the society was in a satisfactory condition, the members amounting to an aggregate of 681. Reference was made to the new departure in the shape of laboratory meetings which had been held during the past session with conspicuous success. Various alterations had been made in the rules to meet the modern development of pathological science and an editor had been appointed. Votes of thanks were passed to Mr. A. Pearce Gould who had acted as president during the latter part of the session, to the retiring vice-presidents, members of the council, and the retiring officers. The following officers were appointed for the session 1900–1: President: Mr. W. Watson Cheyne. Vice-Presidents: Dr. E. Crookshank, Dr. S. Martin, Dr. F. W. Mott, Dr. G. Newton Pitt, Mr. Victor Horsley, Mr. G. H. Makins, Mr. Charters J. Symonds, and Mr. J. H. Targett. Treasurer: Dr. Sidney Coupland. Honorary secretaries: Mr. Charles A. Ballance and Dr. J. Rose Bradford. Council: Dr. F. W. Andrewes, Dr. T. Grigor Brodie, Dr. Sheridan Delépine, Dr. James Galloway, Dr. Archibald E. Garrod, Dr. Herbert P. Hawkins, Dr. R. G. Hebb, Dr. Patrick Manson, Dr. Cyril Ogle, Dr. H. D. Rolleston, Mr. William H. Battle, Mr. Cecil F. Beadles, Mr. H. P. Dean, Mr. A. G. R. Foulerton, Dr. C. D. Green, Dr. F. G. Hopkins, Dr. John McFadyean, Dr. Allan Macfadyen, Mr. D'Arcy Power, and Mr. Frederick C. Wallis.

CLINICAL SOCIETY OF LONDON.

Case of Gastro-enterostomy followed by Pylorectomy.—Septicæmia treated by Anti-Streptococcic Serum and Nuclein.—Conclusion of a case of Graves's Disease.—Annual Meeting.

A MEETING of this society was held on May 25th, Sir R. DOUGLAS POWELL, Bart., the President, being in the chair.

Mr. ARTHUR E. BARKER read a paper on a case of Gastro-enterostomy followed by Pylorectomy and Recovery. The case was that of a woman, aged 55 years, who presented herself in March, 1899, at University College Hospital with very obscure symptoms of partial intestinal obstruction. There was a defined tumour to the left of the left rectus muscle under the border of the ribs. This was variously diagnosed, but Mr. Barker held it to be a growth of the splenic flexure of the colon. The abdomen was opened on this hypothesis by an incision at the left border of the left rectus. The tumour was found to be a carcinoma of the pylorus. Retro-colic gastro-enterostomy was at once performed, from which the patient made a rapid recovery. Five weeks later Mr. Barker removed the whole of the pyloric end of the stomach and closed the resulting openings in it and in the duodenum. Recovery was rapid, and the patient put on flesh steadily and went about as before, eating, as a rule, ordinary food. She died from recurrence exactly one year after the operation. The first operation was done under local (eucaine) analgesia and the second under chloroform anæsthesia. Murphy's button was employed and came away on the twelfth day. The operation was much facilitated by taking it in two stages. The following points were raised: (1) the peculiar position of the tumour, being in the splenic region; (2) the general propriety of pylorectomy; (3) the performance of a preliminary gastro-enterostomy, which was of undoubted advantage, and Mr. Barker thought that it might be made more of a routine procedure; (4) the selection of the anterior or posterior operation, the latter being in most cases as easy as the anterior and, in Mr. Barker's opinion, preferable; (5) the use of Murphy's button, as compared with simple suture, Mr. Barker showing a preference for the latter; and (6) the advantage of local anæsthesia as obviating the vomiting during the operation.—Mr. LEONARD BIDWELL quite concurred with Mr. Barker in preferring the double operation and he quoted some cases on which he had operated in that manner, all of which could be regarded as successful though the growth had recurred later. In one case in which he had performed the operation in one stage the patient died within ten days of the operation from the adhesions in the jejunum, which resulted in a kink. To prevent this accident the loop of the jejunum attached to the stomach should not be too close up to the duodenum. If it were, regurgitation of the bile into the stomach occurred.

He (Mr. Bidwell) advocated Halsted's method of suturing and in only one case had he had the slightest trouble afterwards. As to the interval of time which elapsed between the two operations, he had allowed 18 days and thought that that was a suitable time. In regard to the diagnosis of the early stages of stricture of the pylorus there was at first increased power in the stomach muscle and therefore there might be no dilatation. The absence of dilatation of the stomach rendered the diagnosis more difficult. The duration of life was not very great, but it was longer after the double operation than after gastro-enterostomy alone.—Mr. BARKER, in replying, said he would have liked to have heard more particulars of Mr. Bidwell's cases. As to the duration of life, he was not very sanguine. The operation prolonged life, and the average duration of life was not seven years but perhaps two or three years. Everything depended on an early diagnosis and the courage of the patient to undergo the operation. One thing was quite certain, pylorectomy should never be done for anything excepting malignant disease.

Dr. W. F. VICTOR BONNEY (introduced by Dr. JOHN ABERCROMBIE) read a paper on a case of Obscure Septicæmia treated by Anti-streptococcic Serum and Nuclein. The case was that of a young man who was seized, without any history of previous disease whatsoever, with fever of a persistent type, associated with joint swellings, femoral thrombosis, and abdominal distension. On the forty-second day of the disease rigors began, with a remittent temperature reaching nearly 107° F. on several occasions. He was treated by injections of anti-streptococcic serum, receiving within a period of 17 days 420 cubic centimetres in 42 injections. During this period the temperature fell and the patient greatly improved. A relapse on the sixty-fourth day was treated by injections of nuclein, 1 per cent. solution, in two cubic centimetre doses. He received nearly 30 cubic centimetres in eight days, during which period the temperature fell and the patient rapidly convalesced. He recovered and was now in complete health. The diagnosis, which was obscure at first, was divided between malignant endocarditis, enteric fever, and some obscure form of pyæmia. The first was negatived by the absence of cardiac signs and the second by Widal's test twice applied. Several bacteriological examinations left the matter still unsettled, though Mr. A. G. Foulerton was suspicious of having detected the gonococcus in the blood, but could not, by a mishap, confirm it. Reviewing the whole case, the likelihood that it was a gonococcal septicæmia was not improbable. The serum used was that made by Mr. Bokenham, while Messrs. Burroughs and Wellcome kindly gave the nuclein free. No ill-effects followed the injection of either.—The PRESIDENT remarked on the interest of cases of this kind which ought always to be carefully recorded in order that they might be more readily compared. The patient whose case he had recorded, to which Dr. Bonney had referred, was still alive, but the diagnosis was still uncertain. The cardiac signs disappeared and the patient had had recurrent attacks of fever and of albuminuria.—Dr. ABERCROMBIE remarked that he could not help believing that the treatment by serum and nuclein had the chief share in the recovery of this case, though he had used these remedies in other cases of septicæmia without success, excepting in one instance. As to Dr. Bonney's case, the patient had since presented himself for treatment for urethritis.—Mr. ARTHUR E. BARKER remarked that many cases of gonorrhœal pyæmia came under the notice of the surgeons and he would hesitate to accept the view that this case was checked by the anti-streptococcic serum. Cases of this disease went on to an extreme degree and then got well in a very remarkable way without any remedy. The bacteria probably grew until the soil was exhausted.—Dr. BONNEY, in reply to the suggestion that the recovery was a coincidence, remarked that the patient was getting progressively worse on two occasions and each time that the remedies were given he got well.

Dr. WILLIAM PASTEUR communicated the conclusion and post-mortem notes of a case of Graves's Disease with Bradycardia shown at a clinical meeting in April, 1898. The patient, a widow, aged 67 years, had sufferred from Graves's disease for 20 years and exhibited the disease in a typical form, with tachycardia, when first seen at the Middlesex Hospital in 1836. Under observation the enlarged thyroid dwindled and the tachycardia gradually gave place to marked bradycardia. The demeanour and facial expression were placid and almost apathetic. She said that her voice had altered in quality. She had become very sensitive to cold and rather clumsy with her fingers. It was a question whether the bradycardia was associated with degenerative lesions of the heart, of which there was physical evidence; or whether, with other symptoms just mentioned, it indicated the supervention of myxœdema. The latter was the opinion generally expressed. The patient was re-admitted to hospital in July, 1899, with acute symptoms of heart failure from which she rallied for a time. In January, 1900, she returned to hospital in a critical condition with signs of extreme tricuspid regurgitation and died within 24 hours of admission. The thyroid gland was rather small but not atrophic to the naked eye. Microscopically, parts of the gland appeared fairly healthy, but others showed an extensive round-celled infiltration of the alveolar structure. There were hypertrophy and dilatation of the left ventricle of the heart, but little change was present at the valves and in the coronary arteries. The thymus was not persistent. There were no obvious changes in the brain or meninges. Dr. Pasteur considered that the case afforded valuable pathological evidence of the occurrence of thyroid atrophy in the wake of Graves's disease. The case was of interest in presenting the symptoms of the two diseases in combination. He was of opinion that the bradycardia was more probably related to the condition of the heart than to the thyroid cirrhosis.—Dr. ALEXANDER MORISON said that after hearing Dr. Pasteur he had come to the conclusion that the bradycardia was related in some way to the thyroid disease. He would like to ask if any notable effect resulted from treatment and if it had modified the pulse in any way. The degenerative changes found in the heart were those constantly met with in the opposite condition of pulse and could therefore hardly account for the bradycardia. A systematic examination of the nervous system ought more constantly to be conducted in these cases. His own belief was that they would never be able to speak positively until the nerves' association with the heart could be investigated.—Dr. PASTEUR, in reply, said that the nervous system had not been investigated in this case. As to the results of treatment by thyroid they were negative, and this was not surprising when so much colloid material and cell infiltration were found in the thyroid.

Subsequently the annual meeting was held. The report of the council showed that the financial position of the society was satisfactory and that the work of the society during the past year had been well maintained. Hearty votes of thanks were given to the retiring Vice-Presidents and members of council. The following gentlemen were elected to hold office during the session 1900–1:—President: Sir Richard Douglas Powell, Bart. Vice-Presidents: Dr. Sidney Coupland, Dr. Stephen Mackenzie, Dr. W. Joseph Tyson, Mr. A. Pearce Gould, Mr. John Hammond Morgan, and Mr. Herbert W. Page. Treasurer: Mr. Howard Marsh. Council: Dr. J. Rose Bradford, Dr. C. W. Chapman, Dr. J. K. Fowler, Dr. Archibald E. Garrod, Dr. H. P. Hawkins, Dr. J. A. Ormerod, Dr. H. D. Rolleston, Dr. Harrington Sainsbury, Dr. R. Percy Smith, Dr. J. C. Uhthoff, Dr. A. F. Voelcker, Mr. W. H. Battle, Mr. James Berry, Mr. Stanley Boyd, Mr. L. A. Dunn, Mr. F. S. Eve, Mr. Raymond Johnson, Mr. G. H. Makins, Mr. John D. Malcolm, and Mr. Stephen Paget. Honorary secretaries: Mr. Charters J. Symonds and Dr. Percy Kidd.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—The general meeting of this society was held on May 11th, Dr. Barclay Baron, the President, being in the chair.—Dr. John Macintyre (Glasgow) gave a demonstration upon the Use of the Roentgen Rays in the Diagnosis of Diseases of the Throat, Nose, and Neighbouring Organs, illustrated by numerous lantern slides, photographs, and apparatus. In the first part he dealt with certain matters of technique, alluding especially to the advances made since his last demonstration to the association in 1896. After speaking of the most convenient source of electricity and discussing the relative advantages of Wimshurst machines and coils for Roentgen ray work he mentioned various forms of interrupter, including the Wehnelt and a form devised by himself. He also described various modes of controlling the vacuum in Crookes's tubes, and an ingenious automatic mercurial pump used by him when making his own tubes. Barium platino-cyanide was the salt that Dr. Macintyre found to be the best for screens. The potassium plantino-cyanide,

though more brilliant, was less durable. The use of the screen was gradually coming into greater prominence; but, when photography was necessary, plates requiring only a very short exposure were now being used—a matter of no little importance when the patient was very ill. The second part was devoted to the application of the Roentgen rays to medical work. Speaking first of the application of stereoscopic vision to screen work and photography Dr. Macintyre passed on to the narration of individual cases. He showed how, besides the use of x rays in locating foreign bodies in the œsophagus, the larynx, the antrum, and the bronchi, fractures of the jaws could be seen, enlargement of the cardiac area recognised, and thoracic aneurysm rendered visible when other means of diagnosis had failed. He had also observed enlarged mediastinal glands and the presence of fluid in the pericardium and pleuræ. One interesting point mentioned was the distinct shadow cast by phthisical deposits at the apex of the lung. Examination of the accessory cavities of the nose had also revealed important information; for instance, the presence of a probe passed through the infundibulum into the frontal sinus could be clearly verified. Finally, Dr. Macintyre recommended the systematic examination of patients by the x rays. In many cases this method would only be supplementary to other means of diagnosis, but in a certain few instances he had been able thus to obtain valuable information which could not otherwise have been gained.—A short discussion followed.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—The first annual dinner of this society was held at the White Hart Hotel, Windsor, on May 23rd, Mr. W. B. Holderness, the President, being in the chair.—Amongst other guests the mayor of Windsor, Mr. A. T. Barber, and the ex-mayor, Sir John Soundy, who had granted the use of the Guildhall for the society's meetings, were present.—The Vice-Presidents were represented by Mr. Arnold Thomson and Mr. Startin and the committee by Dr. H. T. Newman and Dr. E. S. Norris. The metropolitan members present included Mr. G. P. Field, Mr. Noble Smith, Dr. Fletcher Beach, and Mr. H. W. Allingham; and in addition to Windsor and Eton the following towns in the neighbourhood were represented: Slough, Maidenhead, Chertsey, Egham, Staines, Ascot, Weybridge, Ashford, Iver, and Bracknell. In all there was a muster of over 40. After the usual loyal toasts had been duly honoured, Mr. Noble Smith, in proposing the "Windsor and District Medical Society," drew attention to its strength and remarkable rate of growth. He also made suggestions as to the possibilities of its further development.—The President after alluding to the immense amount of labour expended by Dr. E. B. Hulbert in organising the society and expressing the universal regret of the members at his resignation, handed him a silver cigarette-box and match-box to correspond as a mark of their appreciation of his work. Both were engraved with a suitable inscription.—Dr. Hulbert responded, expressing his warmest thanks.—Various other toasts having been proposed and acknowledged the proceedings terminated with the National Anthem.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on May 9th, Dr. W. G. Dickinson, the President, being in the chair.—Mr. C. A. Ballance gave a demonstration on the Operative Treatment of Chronic Otorrhœa. Mr. Ballance commenced by dividing chronic otorrhœa into two classes: (1) tractable otorrhœa; and (2) intractable otorrhœa. With regard to the first group, antiseptic irrigation, alcohol instillation, the removal of adenoids in children, and various minor operative measures in the adult were discussed. In intractable otorrhœa Mr. Ballance advocated operation in two stages: (1) the complete mastoid operation for the removal of the disease; and (2) the healing of the operation cavity some seven or ten days later by the application of large epithelial grafts. The advantages claimed were: (1) the immediate healing of the wound; and (2) that now for the first time in the history of the operation the surgeon could honestly promise his patient (*a*) a certain and rapid cure and (*b*) a considerable probability of improvement in hearing. Mr. Ballance also hinted at the boundless possibilities which the success of the grafting of the bony walls of the tympano-antral cavities seemed to offer in the surgery of the bones in all parts of the body and the likelihood that the method might be successful in the treatment of post-suppurative and chronic dry deafness by the application of epithelial grafts to the labyrinth. The address was illustrated by lantern slides.

Reviews and Notices of Books.

Acromegaly. By Dr. MAXIMILIAN STERNBERG, Privat-docent in the University of Vienna. Translated by F. R. B. ATKINSON, M.D., C.M. Edin. London: The New Sydenham Society. 1899. Pp. 138.

THIS volume, one of the latest published by that excellent body, the New Sydenham Society, contains a good account of the somewhat rare disease "acromegaly."

The author gives an interesting and complete account of the "history" of the disease, starting from the original description given by Marie in 1886, although, as it is pointed out, cases of this affection had been previously described under other names.

A brief review is then given of the principal clinical appearances of the disease, but the symptoms are considered in detail further on in the book. Dr. Sternberg has evidently made a careful study of the literature of the subject and has collected the reports of 47 necropsies of undoubted cases of acromegaly, so that the chapter on Pathological Anatomy is made a most instructive one. A comprehensive description is given of the changes found in the bones and some good illustrations, which materially aid in following the descriptions, are supplied in the letterpress. The account of the conditions found in the skull is minutely carried out. With regard to the structure of the bones the author is of opinion that a systematic histological examination of the whole osseous system—certainly a very laborious task—has yet to be undertaken, for in referring to the literature of the subject he found that each author seemed inclined to declare as typical the conditions found in his own case, and the value of these observations was lessened inasmuch as frequently the inquiry was limited to an examination of a few bones or even of only one. Due attention is, of course, devoted to the changes which have been described in the pituitary gland, or, as Dr. Sternberg prefers to term it, "the hypophysis." He considers, however, that the histological conditions met with must be received with a certain amount of reserve owing to the circumstance that the organ possesses a fairly complicated structure and our knowledge of its morphology is not thoroughly exhausted. Further, the interpretation of the reports is also rendered more difficult owing to the fact that the terminology of the pathological anatomy varies in different schools, so that we cannot attach without further consideration a similar meaning to designations which sound identical.

Chapters IV. and V. are devoted to the symptomatology of the disease, its development, course, terminations, the types that are encountered, and the prognosis. Dr. Sternberg's description of the symptoms are clear and concise and Dr. Atkinson has performed the task of translation admirably.

The chapter on the Relationship of Acromegaly to Other Diseases and Conditions will also be found interesting, especially the remarks on "myxœdema and cretinism" and on "gigantism." The author states that it will be found by anyone who collects the cases described in literature as "giants" and considers them strictly according to their pathological conditions that about 40 per cent. of all giants are also the subjects of acromegaly. This proportion suggests the inference of a closer connexion, and after a review of the arguments and cases which have been raised and quoted in favour of the supposition that there is a relationship between the two Dr. Sternberg comes to the conclusion that acromegaly is a well-defined disease, with perfectly sharply-marked characteristics, whilst gigantism is an anomaly of development which in itself has nothing to do with disease, but may occur in connexion with various illnesses and

certainly with universal dystrophies. Acromegaly is one of these illnesses.

The subjects of the etiology and pathology of the disease are fully discussed, stress being laid on the "hypophysis theory." Dr. Sternberg is of opinion that notwithstanding the reserve that must be maintained regarding the histological results met with in the hypophysis, the connexion between the course of the disease and the post-mortem appearances is so striking that it adds, no doubt, an important support to that view which sees in the cessation of the normal function of the hypophysis the cause of acromegaly. "Whatever may be imagined as to a closer connexion it is at present entirely left to conjectures which are as numerously present in the literature as they are unproved." An especial difficulty, which is at present insurmountable, arises from the fact that there is no doubt that tumours of the hypophysis may exist without acromegaly.

One of the best chapters in the book is that dealing with diagnosis, and we need only refer to the list of diseases which the author states may be mistaken for acromegaly to appreciate the great care with which he has written his book. To readers interested in this subject we can confidently recommend a perusal of this work.

On Neuroma and Neuro-fibromatosis. By ALEXIS THOMSON, F.R.C.S. Edin., Assistant Surgeon to the Royal Infirmary, Surgeon to the Deaconess Hospital, and Lecturer on Surgery, Edinburgh. With 20 plates. Edinburgh: Printed by Turnbull and Spears. 1900. 4to, pp. 168. Price 21*s*.

NEW growths in connexion with nerves are rare, yet these tumours are so striking that medical literature contains records of a large number of cases. The attention of Mr. Alexis Thomson seems to have been directed to this interesting and important subject by a very remarkable series of 15 cases which were in the wards of the Royal Infirmary, Edinburgh, within six years.

In 1803 Odier of Geneva introduced the name "neuroma" for tumours forming in connexion with nerves. In 1829 a valuable paper was read before the Medico-Chirurgical Society of Edinburgh by William Wood who gave a careful account of the clinical and pathological characters of the disease and records 24 cases which he had collected. Various other papers on the subject have from time to time appeared, but in 1849 was published an important work on Neuroma by R. W. Smith of Dublin. His descriptions have been copied into all text-books since, and though Virchow in 1863 distinguished between the true neuroma which consists of true nerve tissue and the false neuroma which is derived from the connective tissue of a nerve, yet the term "neuroma" has very conveniently been applied to all tumours arising in connexion with nerves. The true neuroma, composed chiefly of nervous elements, is of extreme rarity, and only five certain cases have been put on record; they have probably all been connected with the sympathetic system, and abstracts of the notes of all the cases are given in Mr. Thomson's work, and Dr. Knaus's remarkable case is figured. The "false neuromata" are the really important growths and the author classifies them thus: (1) circumscribed tumours; (2) diffuse overgrowths of the connective tissue of nerves—that is, "neuro-fibromatosis"; (3) traumatic neuromata; and (4) enlargements of nerves in leprosy and syphilis.

The circumscribed variety of the false neuroma may be either innocent or malignant. The innocent growths are far from uncommon and one form is well represented by the "painful subcutaneous tubercle." The malignant variety is a sarcoma and it usually occurs in the prime of life—from 20 to 40 years of age; it is much rarer than the innocent form, and Mr. Thomson has collected 12 cases of well-authenticated primary sarcoma of nerve. Of these in five cases recurrence occurred and death ensued, and in only two has removal of the tumour been followed by two years' freedom from recurrence. It is a remarkable fact that in half the cases the great sciatic nerve was affected.

Of even greater interest than neuromata is the condition which has been called "generalised neuro-fibromatosis." As the author remarks, "the clinical and pathological records of this remarkable disease are so numerous that there is no want of material upon which to base" a description. The nerves are the seat of a great number of tumours and are also diffusely and unequally thickened. In a transverse section of such a nerve-trunk there is seen to be a formation of new connective tissue within the primary bundles of nerve fibres. These changes may occur in the cerebral nerves as well as in those arising from the spinal cord. Curiously, however, the meninges of the brain and cord are never affected, although they correspond to the fibrous tissue of nerves. The tissue in the nerve which appears to suffer most is the endoneurium. Different observers disagree as to the effect of the fibromatosis on the nerve fibres, but Mr. Thomson is satisfied from the special investigation of two cases that degenerative changes are present. As to what nerves are affected the author tabulates 45 cases in which the cranial nerves were implicated and of these the vagus was involved in 29 instances and the fifth nerve in 12, but no nerve was exempt, though it has been stated that the olfactory, optic, and auditory nerves are never affected.

Another form of neuro-fibromatosis is that called "the plexiform neuro-fibroma." It may be looked upon as a fibromatosis confined to the distribution of two or more contiguous nerves or of a plexus of nerves. Histologically, the condition is identical with generalised neuro-fibromatosis, and the two conditions may co-exist in the same individual. Though the disease is rare 62 cases have been collected. By far the most frequent situation of these growths is the subcutaneous tissue of the head and neck in the area of distribution of the fifth cranial and the superficial cervical nerves.

The third variety of neuro-fibromatosis is that form of tumour which is usually called "molluscum fibrosum," and the connexion of this new growth with disease of the nerves was first pointed out by von Recklinghausen in 1882. In this disease the new fibrous tissue is for the most part situated between the bundle of nerve-fibres and the investing perineurium. These skin tumours may occur combined with other forms of neuro-fibromatosis. A still more remarkable condition associated with an increase in the fibrous tissue in nerves is that known as "elephantiasis neuromatosa." This was specially described by Mott of New York in 1854 under the name "Pachydermatocele." It includes those forms of neuro-fibromatosis in which in addition to the fibromatosis of the cutaneous nerves there is also a well-marked and diffuse overgrowth of the skin and subcutaneous tissue in a particular region of the body. The disease is of congenital origin and it increases slowly at first but often more rapidly after puberty. The special seat of the overgrowth is in the pons reticularis of the corium. In other cases neuro-fibromatosis is associated with pigmentation of the skin.

It happens not rarely that patients who are the subjects of neuro-fibromatosis develop sarcoma in the diseased nerve-tracts. This has been well called "secondary malignant neuroma." It chiefly manifests itself by great local malignancy, though exceptionally visceral metastases may occur. In a few cases multiple tumours of the brain have developed in patients with one or other variety of neuro-fibromatosis, but the author considers that this combination of tumours of the central nervous system with

fibromatosis of the nerves is only a coincidence. Mr. Thomson has tabulated the particulars of 77 cases of neuro-fibromatosis, so that reference may be made to them very easily.

The author in summing up his conclusions with regard to this disease tells us that he is inclined to think that it arises before birth or in early childhood, that it is sometimes inherited (as shown by 10 cases which he has collected), that mental deficiency is often also present, and that sex seems to have no influence. He is able to suggest no satisfactory explanation of its actual cause but regards it as a developmental disease. Clinically there is wonderfully little to be said about neuro-fibromatosis. As a rule the tumours are quite insensitive—a striking contrast to the solitary tumours of nerves. Occasionally one tumour, especially where exposed to pressure, may cause pain but this may vary from day to day. It happens, but only very rarely, that the enlarged nerve may press on the brain or spinal cord close to its origin, and so symptoms may arise of pain or paralysis.

A chapter is devoted to detailed accounts of the cases which have come under the author's personal observation, and in the last chapter the traumatic neuromata are discussed. An extensive and valuable bibliography is given. Unfortunately there is no index; this is a most regrettable omission, for every scientific work loses some of its value if the contents cannot be readily referred to.

The 20 plates are carefully executed; they represent well the gross and minute anatomy of the disease. The book is clearly printed on good paper, but the quarto form is certainly not so convenient for general use as is the octavo.

There can be no doubt that Mr. Thomson has made a very valuable contribution to our knowledge of an important class of tumours which have hitherto hardly received their due share of recognition.

Rhinoplastic Operations, with a Description of Recent Improvements in the Indian Method. By D. F. KEEGAN, M.D. T.C.D., F R.C.S. Eng., Indian Medical Service (retired). With 21 Phototype Portraits and 11 Engravings in the Text. London: Baillière, Tindall, and Cox. 1900. Roy. 8vo. Pp. 72. Price 5s.

DR. KEEGAN'S thoroughly practical manual is to some extent an after-growth and expansion of his article on Rhinoplasty which appeared in THE LANCET of Feb. 21st, 1891 (p. 419). At that time he had performed a large number of rhinoplastic operations in the Charitable Hospital at Indore and had devised the modification of the ordinary procedure which it is the object of the present volume to describe more in detail. In some respects the conditions under which he worked were more favourable than those with which British surgeons have to deal, his patients being mutilated not by disease but by cutting instruments. This form of cruelty, although rare in modern Europe, is nevertheless of great antiquity. Many of our readers will recollect the passage where Virgil describes the visit of Æneas to the under-world and his meeting with his friends who had been killed at the capture of Troy.

> Deiphobum vidit lacerum crudeliter ora,
> Ora, manusque ambas, populataque tempora raptis
> Auribus, et truncas inhonesto vulnere nares.

Dr. Keegan mentions that in modern India nose-cutting is a not infrequent form of vengeance for matrimonial offences, and the Trojan legend affords a curious parallel, for Deiphobus after the death of Paris became the consort of Helen, the runaway wife of King Menelaus, and was eventually killed by the aggrieved husband. The distinctive feature of Dr. Keegan's operation, for which he modestly makes no claim of priority, consists in this, that whereas formerly the nasal defect was covered only with a single layer of skin he found means of making firm, open-standing nostrils, lined internally with skin taken from over the nasal bones and covered externally in the usual way with skin raised from the forehead. The difficulty has always been to ensure the prominence and shapeliness of the nose, and to prove that this problem has now been solved 21 phototype portraits of seven patients are introduced, four of them being shown both full-face and in profile. We have no hesitation in strongly recommending the book as the work of a skilful operator. The history of rhinoplasty by means of a forehead flap is not without interest to British surgeons, as it was first practised in Europe by Mr. Carpue of London, of whose cases Dr. Keegan gives a summary. The volume is well printed and its handsome appearance reflects credit on the publishers.

JOURNALS AND REVIEWS.

Revue de Gynécologie et de Chirurgie Abdominale. Tome IV. Nos. 1 and 2. January—February, March—April, 1900. Paris: Masson et Cie.—The first number of this review for the current year contains a most interesting paper by Professor Cornil upon the Anatomy and Histology of Tubal Pregnancy, founded upon a careful examination of seven cases. MM. Jayle and Delherm contribute a study of Extra-uterine Tubal and Intra-ligamentous Gestation after the fifth month, with details of 29 cases collected from the literature and including two of their own observation. M. Vidal writes upon the Technique and Results of Some Conservative Operations upon the Uterine Appendages. A paper upon the Dangers and Accidents of Incomplete Hæmostasis is contributed by M. Rebreyend. A Critical and Historical Study of the Treatment of Fibromata of the Uterus by Electricity by M. A. Zimmern affords a good account of the latest views upon the subject. M. François Neugebauer adds another series of 29 observations of Error of Sex to the 50 cases already recorded by him in the April number of the review for the year 1899. In the second number is a short paper by Professor Pozzi upon Four Cases of Torsion of the Dilated Fallopian Tube. The condition associated with the torsion was in three of the cases a pyosalpinx and in one a tubal gestation. The question of making traction upon a Fibromatous Uterus during Abdominal Hysterectomy is discussed by Professor Reverdin. He describes in detail the method employed by him of suspending by means of a special apparatus large and heavy fibroid tumours during the progress of an operation undertaken for their removal. An interesting case of Fistulous Communication between the Sigmoid Flexure and the Vagina is recorded by M. Xavier Delore. The fistula was closed by the following very ingenious method. The recto-vaginal septum was split up to the site of the opening and after the adherent piece of gut had been separated from the vagina its anterior wall was drawn down and attached to the anus. The anterior wall of the rectum was then cut through up to the level at which it had been separated from the posterior vaginal wall. In this way the piece of bowel above the site of the fistula was made to open into the rectum, while the intervening portion of sigmoid flexure was, as it were, short-circuited. The result was good. M. Fontan continues his series of articles upon the Surgical Treatment of Abscesses of the Liver invading the Thoracic Cavity. The remaining part of the numbers is taken up with analyses of current literature.

VICTORIA HOSPITAL, FOLKESTONE.—The Duke of Cambridge on Saturday last laid the foundation-stone of a new wing to this hospital. It is to commemorate the Queen's Diamond Jubilee, will cost £6500, and will consist of two new wards of 14 beds each, affording additional accommodation which is greatly needed.

THE LANCET.

LONDON: SATURDAY, JUNE 2, 1900.

THE papers read at the last meeting of the Royal Medical and Chirurgical Society were of unusual interest. The topics discussed, like the enveloping British forces now invading the Transvaal, covered a wide field, which had to be traversed with great celerity in order to bring the discussion within the limits of the time at the disposal of the speakers. Any attempt on our part to pass the subjects in review would only prove futile, but we select a few points for comment.

The first to address the meeting was Mr. CLINTON DENT whose remarks had the merit of being both practical and suggestive. Sir WILLIAM MACCORMAC followed Mr. CLINTON DENT with an address which was published in our issue of May 26th. Sir WILLIAM MACCORMAC'S observations dealt mainly, of course, with the surgical aspects of the present war. He detailed the conclusions which he had formed thereon, with which those who have read the series of surgical notes which he forwarded to THE LANCET from the actual scene of warfare, while the facts and the impressions he derived from them were still fresh in his mind, are already acquainted. But Sir WILLIAM MACCORMAC having had leisure to arrange his thoughts was enabled in his address to summarise and supplement his original observations by a running commentary. The impression that must be derived from reading his address is that it contains the results of thoughtful experience set forth in admirably simple and clear language. Terrible as war always must be, Sir WILLIAM MACCORMAC is reassuring because he presents a vivid and realistic picture of the far less serious and fatal injuries inflicted by modern rifled arms; while he inculcates the hopeful lessons to be learnt from our recent experience as to how much may be expected by abstention from operative interference. In what Sir WILLIAM MACCORMAC has to say about abdominal surgery in the field most persons will thoroughly concur. After a big battle by no reasonable provision beforehand can an adequate amount of surgical aid to the wounded be supplied at once, although the modern methods of field medical organisation are probably the best that have yet been devised for stripping the battle-field of its wounded. The pressure after an action is so great and the energies and resource of the surgeons are so overtaxed as not to admit of early or prolonged operations. We fully concur, too, in what Sir WILLIAM MACCORMAC has to say about operations for the removal of bullets. The reasons which have been recently put forward for their removal where they are not giving rise to pain, trouble, or inconvenience are, it seems to us, altogether insufficient. Again, in his expressed views about the position of female nurses at the seat of war Sir WILLIAM MACCORMAC is eminently sound; a moving army in the field with an enemy confronting it is emphatically not the place for women, and no general or commanding officer would ever willingly consent to their being there. But we especially desire to express our hearty concurrence in what Sir WILLIAM MACCORMAC has urged about the duty of Governments to send properly accredited military medical officers as military medical *attachés* to the seats of war. It should be an established rule to do this, for every military power, especially those where conscription is in force, is concerned in providing the best possible system of medical administration. The military *attaché* accompanying the headquarters staff may know very little of the military operations, but he would always find a welcome from his brother medical men who would have nothing to conceal from him with respect to medical organisation.

Mr. CLINTON DENT'S address also calls for attention—an opinion in which all will concur who heard it or who have perused the summarised report of it in our issue of May 26th, p. 1515. It deserves careful study because it deals with a number of details which do not readily lend themselves to a hasty purview or brief comment. Military medical and sanitary authorities alike will probably agree with Mr. DENT in what he has to say about accommodation for the wounded. Churches, schools, and public buildings are, as a rule, quite unfitted for such a purpose and are certainly inferior to temporary canvas structures. For one thing, most permanent buildings of this nature are usually quite insufficiently ventilated; and whether a cathedral or a schoolroom has to be occupied the free admission and movement of fresh air are essential. In the views of Mr. DENT concerning additional air space in marquees, bedsteads of less width than that of the regulation pattern, the provision of flooring, and the desirability of having a more permanent and special kind of operating theatre than a tent, we concur, and we trust that some of his very sensible and practical suggestions will bear fruit in the future. We have possessions in all parts of the globe and in every sort of climate and never know where our next war will be. Military success often depends upon the mobility of our forces; and whatever we provide in the way of hospital stores and equipment has to be packed and transported to the scene of action and adapted, as far as practicable, to the varying circumstances of the country and campaign. Those responsible for medical administration must therefore often have before them very difficult problems—which fact should ensure a ready hearing for wise criticism.

WE have several times alluded in our columns to the Consultative Medical and Surgical Institution of Birmingham, the projection of which has called for great and misspent energy from Mr. ARTHUR CHAMBERLAIN, who shares with the Birmingham Hospital Saturday Fund the responsibility for a curious departure in medical practice. We dealt with the matter fully in a leading article which appeared on May 20th, 1899, under the heading, "The Degradation of Consultation." The scheme has now become a fact, for we read in the advertisement columns of a lay contemporary

that the institution was opened on Monday, May 21st. The advertisement, which we print in another column (see p. 1633), states that the institution has for its object "to lessen the strain upon hospital charity by providing, on terms within and under conditions suitable to their pecuniary means and position, medical and surgical aid to those who would otherwise seek it gratuitously or be unduly taxed by paying the usual consultation fees." To carry out this object this institution offers to those in need of it the services of a consulting medical practitioner at the reduced rate of half a guinea per consultation. In the original scheme there were to be two such medical officers, but we believe that as yet only one officer is provided, though if the supply of cheap consultants were unlimited the objections to the scheme would be as forcible.

Birmingham is a shrewd city which has made its mark in the world by its quick solution of economical difficulties and by its orderly management of municipal affairs, and we believe that a community which has shown itself so distinctly level-headed will see at once that the Consultative Medical and Surgical Institution offers no advantages to the public whatever. The general advice that the public will obtain for half a guinea, however sound, will not be the kind of advice for which those who can afford it are wont to pay proper fees; while to those who cannot afford to pay two guineas or one guinea what they will get for a smaller sum might prove of but small value in highly special or obscure conditions. The scientific opinion upon all sorts of pathological conditions of one or two gentlemen cannot in these later days of medicine be as valuable, as informative, and as little open to error as the aggregate advice given by the staffs of general hospitals and special hospitals. This is obvious, however well equipped in many scientific directions the cheap consultant officers may be; whilst if it should chance that their endowments are not on the face extraordinary acceptance of the post will lead to the suspicion that desire for employment has overcome modesty. All this will be obvious to Birmingham, and we believe confidently that the people will decide for themselves that they must see a genuine consulting surgeon or physician if they want to have genuine benefits from a consultation. To ask the advice of an institution which will be unable to guarantee the services of men having beneath their hands the proper fields from which to glean their experiences will be felt to be an idle and dangerous course; and if this does not appear at once it will on the first occasion when a man finds himself consulting for presbyopia the same gentleman who has already given ten-shillings-and-sixpence-worth of specialised opinion upon a neighbour's fractured patella. The public recognises that the general practitioner is able to treat such conditions and only looks for the services of a consultant when the circumstances are exceptional. And, equally, the public will find it curious that exceptional knowledge of such a wide range should be centred in one or two gentlemen without hospital appointments.

The general practitioner in Birmingham can help the sick in Birmingham as he is helping the sick throughout the kingdom. Under all ordinary and most extraordinary circumstances, he can do for them what their condition requires and he can tell whether they need further advice than his own. For, unlike the officers of the Consultative Medical and Surgical Institution, he has no need to wear the appearance of knowing everything. If the case is one where consultation with some man of wide or special experience, some man with all the peculiar advantages of being in touch with a hospital, is necessary, the general practitioner can decide how such consultation should be obtained. Few families require the services of a consulting surgeon or consulting physician very frequently, and the expense of paying the usual fee is one which, when regarded as an extraordinary item, is not crippling to persons unless they are really poor. Where, on the other hand, the payment of two guineas or one guinea is entirely out of the question the general practitioner will direct them into their right course. Such patients can go to a hospital, or they can ask their medical man to represent to the consulting physician that there are considerations in the case which would make it a kind thing to waive a portion of the fee. Most consulting physicians and surgeons in Birmingham will see patients at a reduced rate if the propriety and humanity of doing so are proved to them. And the medium through whom the consultant medical men should be approached is the general practitioner, who alone can say whether a case is one demanding particular attention, and who can generally estimate with some accuracy the pecuniary position of the patient. The intervention of the general practitioner will secure that only those borderland cases reach the consultant which clearly belong neither to the class from which hospital patients should be drawn nor to the class which can easily pay full fees.

IN THE LANCET of May 19th (p. 1420) we published an address which was recently delivered before the annual meeting of the Gloucestershire Branch of the British Medical Association at Cheltenham by Dr. ROBERT SAUNDBY who selected as his subject "The Modern Treatment of Diabetes Mellitus." Dr. SAUNDBY'S previous writings on this disease are well known, and his remarks on this occasion are particularly worthy of perusal and careful consideration. In discussing briefly the "theory of diabetes" he laid stress on certain points which have not received from most observers the attention which should be paid to them. It is well known that the withholding of carbohydrate food fails to stop the excretion of sugar in severe cases of diabetes. An explanation of this phenomenon has been adduced by Dr. PAVY and others by demonstrating that the albuminous molecule whilst undergoing decomposition into urea, water, and carbonic acid splits off a carbohydrate molecule from which sugar is formed. The resulting sugar and urea bear a definite relation to one another, so that if we know the quantity of urea excreted in 24 hours we can calculate the amount of sugar formed in the body from the decomposition of albumin. Yet if the tissues continued to consume a normal proportion of sugar all of this should be used up in the body. This important consideration has not been sufficiently recognised in framing a theory as to the morbid factors which bring about the condition of diabetes mellitus, and

therefore the usual conception that the essential cause of the disease is a derangement of the glycogen-storing function of the liver caused by bodily or mental shock or other *noxa* has to be modified by postulating a further failure of the sugar-destroying function of the tissues. It is difficult to explain, as Dr. SAUNDBY points out, how the tissues come to lose, partially at all events, their power of assimilating sugar, but there seems to be reason to believe that it is directly caused in some way by the excess of sugar which reaches them. When this quantity is restricted by careful diet many diabetic patients show after some time an increase of sugar-destroying power. Dr. SAUNDBY very concisely sums up his inferences as to the theory of diabetes thus: "We have therefore arrived at the conclusions that under the influence of certain agencies ..... the liver loses its power of storing glycogen; in consequence the tissues gorged with sugar suffer a diminution of their power to consume that substance; and finally glycosuria ensues which becomes persistent and increasing unless arrested by treatment." Equally interesting and precise are Dr. SAUNDBY'S remarks on the pathogenesis of diabetes mellitus, but we have not space to comment on them here, suffice it to say that he believes that there are three principal organs to which, upon more or less important grounds, we look for the seat of the original mischief to which the functional disturbance of the liver must be attributed. These are the nervous system (more especially the brain, the medulla oblongata, and vagi), the pancreas, and the liver.

It is, however, to that part of Dr. SAUNDBY'S address which deals with the treatment of diabetes mellitus that we would particularly direct the attention of our readers. There is, unfortunately, an absolute consensus of opinion among those who have most experience of this disease that no drug hitherto suggested has any influence upon its course, and therefore the treatment must be entirely dietetic. It is by no means an easy matter to draw up a diet table which will satisfactorily fulfil all the indications for the well-being of the patient, but Dr. SAUNDBY succeeded in placing the subject before his hearers in a manner succinct and most practicable. In the first place he pointed out that attention must be paid to quantity as well as to quality, for it is more than probable that such untoward results as are alleged to have followed sometimes the use of strict diabetic diet were due to excessive quantities of albuminous food. The quantity of food that a patient should consume is calculated in heat units. The usually accepted heat values of the ordinary elements of food are, roughly, for one gramme of albumin, four heat units; for one gramme of carbohydrates, four heat units; for one gramme of fat, nine heat units; and for one gramme of alcohol, seven heat units. A person weighing 10 st. requires daily on slight work an alimentary value of 2450 heat units. In addition a diabetic subject must receive a quantity of food equal in heat units to the amount of unconsumed sugar which he secretes.

On this basis tables are given by Dr. SAUNDBY indicating the quantity and nature of food substances which may be given to diabetic patients so as to fulfil the above requirements. The amount of sugar passed by the patient has to be estimated frequently and the diet altered in accordance with the results obtained. This necessary analysis may perhaps seem a stumbling-block, but by means of the apparatus now manufactured the necessary operation may be successfully accomplished in a very few minutes. Especially noteworthy are the "extras" which may be gradually added to the diet of a diabetic patient, the apportioning of them being strictly governed by the results of the urinary analysis. The monotony of the *régime* may thus be considerably modified, much to the patient's satisfaction, but, as the lecturer maintained, for safety to be assured in making these additions to the diet each extra must be allowed separately, and no further change should be permitted until the result of consuming the new articles of food has been tested by careful analysis of the urine. When a sufficiently varied diet has been reached a sternly uncompromising attitude should be maintained upon the question of further concessions. Having thoroughly followed Dr. SAUNDBY'S arguments and studied the illustrative cases quoted by him we believe that practitioners will find that they have acquired much valuable information as to the dietetic treatment of diabetes mellitus; the success of any such therapeutic measure being governed by the care and completeness with which it is applied. Dr. SAUNDBY has done good service in laying his views with such clearness before the profession.

THE fluctuations of the money market are, at least in their minor details, a little outside the comprehension of the majority of our profession who might even find some difficulty in defining accurately a "bull" or a "bear." And, as a rule these fluctuations do not concern us as a profession, but when our contemporary the *Times* reports, apparently in all seriousness, that the progress of plague is beginning to exert a prejudicial influence upon the buoyancy of certain stocks we feel compelled to ask how far such a condition is justified by facts. Naturally our chief concern is with our own country and we are anxious to consider whether there is a likelihood of the scenes associated with the Plague of London being ever re-enacted in our midst; for this is the vision which the Stock Exchange seems to have conjured up. Is there anything in the behaviour of plague as it is manifesting itself among Europeans at the present time which would lead us to view the immediate future as regards the British Isles with misgivings? It is a serious fact that to answer this question with a direct affirmative or negative would be to go beyond what the facts justify.

Since the recent appearance of bubonic plague in the East the disease has been studied in almost all its aspects by representatives of one or another country, and although our own Royal Commission has not yet said its last word we are in possession of knowledge which enables us to understand at least some of the means by which the disease may be spread and its presence determined. The discovery of the specific bacillus has helped us materially, and although we are perhaps as far as ever removed from an understanding of that mysterious combination of causes which, after a lapse of so many years, has bestowed upon plague a certain power of epidemic diffusion, we seem to have a more correct conception of the multitudinous forms in which probably, in the first instance at least, the disease may stalk abroad. Not a few recent

facts—as indeed does the whole history of plague—point to the enormous influence which what is known as "pestis ambulans" may exert upon the diffusion of this disease, and if the true detailed history of plague were known it would be found in the majority of cases to have spread through the medium of unrecognised cases; in other words, the danger is from the unknown rather than from the known, and under the head of the unknown we must, of course, have regard to the influence of infected rodents. As an instance of the possible operation of the unsuspected agency, we may refer to the story of the voyage of the s.s. *Golconda*, which is told by Dr. BULSTRODE in the current report of the Medical Officer of the Local Government Board. The *Golconda* arrived at Plymouth with a case of pestis ambulans on board, and the history of the patient pointed to the fact that he had suffered from plague since the vessel left Colombo, and that he had been ashore at the ports of call on the way home. If that patient had given rise to plague at any of these points it is not unlikely that the source of the disease would never have been ascertained. He had started from a port which was not at that time recognised officially as infected with plague and hence quarantine would have been useless to prevent the occurrence, and of course he was not known to be suffering from plague when he went on shore. How can importations of this character be guarded against? Certainly not by quarantine, unless the quarantine be directed to the whole world, and together with the prohibition of plague we prohibit the food which maintains our lives. In so far as this country is concerned we must place our reliance upon medical inspection, coupled with a notification forwarded to our inland sanitary authorities of all those who may be considered to have been exposed to infection. The destruction, as far as may be possible, of rats upon ships from infected or suspected localities or infesting the docks and wharves of our ports, must also be undertaken. Our port medical officers of health must in these days throw a wide net. They have ample powers and they must interpret those powers liberally. True this port sanitary net may not keep back every case of pestis ambulans; it probably will not. But everything that passes through this net will be observed and any after-developments will be promptly checked, assuming that our inland sanitary authorities are alive to their responsibilities.

At the present moment, so far as the condition of Europe is concerned, there is little to excite alarm in England, and the presence of plague within a few days' steam of our ports is not yet an immediate source of danger, though, of course, the likelihood of recrudescence in the human species, or of its persistence in rodents, must be borne in mind. In this connexion the recent experience of Alexandria is not without its lessons. Here we find a heterogeneous population of about 320,000 persons living under conditions which are far from sanitary, but although plague obtained a decided footing at this port, when attacked by European methods it failed to spread; and Alexandria is to be regarded as one of the most important gates of Europe through which a large proportion of possible infection must make entry. So, too, with regard to the behaviour of plague amongst Europeans at the present time, there are no reliable indications that the disease is either of a highly infective or explosive type, and we may with some reason assume that before this country is seriously affected with plague we are likely to have marked manifestation of the disease upon the mainland of Europe. Plague can only to a very limited extent be classed with cholera, and we know of no explosions of plague such as are matters of history in the case of cholera. Moreover, there is no well-authenticated instance of water-borne plague on record. Perhaps the disease with which plague may be most reasonably compared is typhus fever, and it may be inferred that the progress of our sanitation has at least had some effect in controlling this latter disease, even though, as we are from time to time reminded, it is still with us. It is, of course, conceivable that both plague and typhus fever may one day resume their old epidemicity, but even if this be so we find difficulty in believing that diminished overcrowding, the notification and isolation of disease, and our ability through our sanitary organisation to seek out unrecognised cases will count for nought. As regards the oscillation of the pecuniary pendulum, we can well understand that local outbreaks of plague may have some influence upon the stocks connected in one or another fashion with the commerce of the invaded areas, but apart from this we see at present no sufficient reason for disturbing our securities. It has to be accepted that plague has assumed pandemic proportions, and its presence in Australasia and in North and South America offers much food for reflection, but the hour of actual apprehension has not arrived for the British Isles.

Annotations.

"Ne quid nimis."

THE USE OF HORSEFLESH AS A FOOD.

THE gradually extending use of horseflesh as an article of daily consumption in Germany and the circumstance that many of our brave troops have been compelled to use it as a diet more or less completely replacing beef and mutton for many weeks together in Kimberley and Mafeking make opportune an article upon its effects by the well-known physiologist Ed. Pflüger which is published in the May number of his *Archiv für Physiologie*. Professor Pflüger's experiments were instituted on dogs to determine the metabolism of the body and the capability of obtaining a full amount of work out of the animal on a diet of pure, or nearly pure, albumin. With this object the well-boiled muscles of fish were given, which the animal ate with relish, but which, from the difficulty of freeing it from bones, had to be discontinued, vomiting and staining of the fæces with blood resulting from its use. Horseflesh next suggested itself as representing albumin with an extraordinarily small proportion of fat, yielding, in fact, only about 1 per cent. of ether-extract. This, carefully cleansed from tendon and any apparent adipose tissue, was given to a dog after being passed through a mincer either in the fresh state or after sterilisation and division into equal blocks which kept well. The immediate effects were that diarrhœa set in, which continued as long as this kind of meat was supplied and, in addition, under nearly similar conditions of work, the daily loss of nitrogen by the bowels was found to be doubled, or more than doubled. Professor Pflüger then made inquiries

of the keepers of the Zoological Gardens at Cologne, and found that it was generally known that the use of horseflesh caused diarrhœa in all predatory animals, on which account it had been very generally given up and the flesh of cows, which caused no disturbance of the bowels, had been substituted for it. He found, too, that the same effects followed its use whether it was eaten raw or had been first boiled. Cats were less disturbed than dogs, though still to a noticeable extent. Investigations were now undertaken to determine whether the effects observed were due to the want of fat or to the presence of the large quantity of glycogen which horseflesh is known to contain. Therefore mutton fat from the region of the kidneys in the proportion of 750 grains to each 4 lb. 4 oz. of the meat was added with immediate good effects, for the dog at once began to pass well-formed fæces. The same result followed the admixture of ox fat in like proportion, but pig's fat was much less effective in arresting the diarrhœa. The question arose whether the diarrhœa resulted from the mere poverty of fat in horseflesh or from the presence of some poisonous constituent in it to which fat proved an antidote. Further experiments in which horse-fat was mingled with ox-flesh and administered to the animal as a diet caused no diarrhœa, hence it was concluded that there was no poisonous constituent in horseflesh. Experiments made with starch in the form of rice pap reduced but did not prevent the diarrhœa caused by the exclusive use of horseflesh. When the diet of horseflesh was continued for many months the addition of even considerable proportions of rice-pap and fat had but little effect in controlling the diarrhœa. Next an endeavour was made to determine whether the toxic agent was contained in the water in which the finely divided meat had been boiled. This was separated by passing through a sieve, but the addition of this fluid had no injurious effect whilst the meat-pap left on the sieve produced diarrhœa. In other words what the French would call the bouilli was poisonous whilst the bouillon was not. The boiled meat was now subjected to the action of alcohol and experiments were made with both the material that was precipitated by alcohol and with that which was obtained by evaporating the alcohol to dryness. The results showed that the poison was not contained in the precipitate caused by alcohol but in the material left on the evaporation of the alcohol. This material was again treated with ether. The ether dissolved part of the alcoholic extract and left a remainder. Experiment again showed that the toxic agent was contained in the material dissolved by the ether but its action had become considerably enfeebled, probably owing to its decomposition. A quantitative analysis of the ether-extract seemed to show that it was composed of about three-fourths of lecithin and one-fourth of neutral fat and cholesterin. This certainly does not afford any information in regard to the exact nature of the toxin but it indicates the path for further research and leads Professor Pflüger to suspect that it may consist of neurin or some modification of that poisonous agent. He concludes with some suggestions for cooks in beleaguered garrisons who are reduced to horseflesh as food, which coming from the pen of one of the most distinguished living physiologists, deserve consideration. In one mode of dressing the horseflesh is converted into a pulp and for every two pounds about three-quarters of an ounce of ox fat or mutton fat taken from the region of the kidneys is served up with a sauce of meal as a hash. Another is to cut it into collops, boil it in water, throw away the broth, and serve the meat with a fat sauce. Beer, wine, tea, or coffee may be taken with it. A third is to convert it into a pulp, add a tenth of its weight of rice and a fortieth of its weight of fat, and cook by steaming; or, lastly, it may be beaten up with plenty of fat and eaten with an oily sauce.

THE TENURE OF OFFICE OF MEDICAL OFFICERS OF HEALTH.

IN THE LANCET of May 19th we drew attention in a leading article to the disabilities under which provincial medical officers of health often labour by virtue of the fact that the insecurity of their offices renders its difficult for them to perform their duties in a manner satisfactory at the same time both to their own self-respect and to the public health, and we referred to the Bill now before Parliament which has for one of its objects the creation of permanent appointments. We expressed our sympathy both with the spirit of the Bill and with the efforts which were being made by certain medical practitioners for furthering its objects, but we also suggested that there might be difficulty in securing the passage of the Bill through Parliament in its present shape on account of its somewhat far-reaching nature. Moreover, we expressed doubts whether it was altogether desirable in the true interests of the profession or of the public health that an effort should be made to render permanent part-time appointments carrying with them such insignificant salaries as £10 to £50. We regret to find, as will be seen under the heading of "Correspondence," that Dr. J. Groves, the well-known medical officer of health of the Isle of Wight Rural District, regards our remarks as "ungenerous." This is the last form we intended them to take. We are quite aware of the difficulty to which our correspondent draws attention of persuading "local authorities to pay salaries commensurate with the dignity of the office"; indeed, we see no prospect of the smaller and poorer authorities ever being able to do so, and we are afraid, too, that the attempt to compel them to saddle themselves with permanent appointments will also fail. It is partly for this reason and because we think that £10 appointments are inconsistent with the position which the medical officer of health should occupy that we rather advocate the creation of combined appointments carrying with them adequate remuneration; at any rate, we incline to the view that it is appointments such as these which should, in the first instance at least, be rendered permanent. We question the practicability of carrying the present Bill through Parliament and we still advise the modification which we have suggested. Moreover, the loss of office by an officer who devotes his whole time to public health work and who derives his livelihood from it is a much more serious affair than the loss by a general practitioner to whom the paltry pay he receives as medical officer of health is a relatively insignificant matter. It is surely desirable in the interests of the profession that there should be at least some pecuniary and other limitations to the creation of permanent appointments and that some check should be placed upon sanitary authorities anxious to rid themselves permanently of their responsibility in the very cheapest manner possible.

SHELL-FISH AND POLLUTED ESTUARIES.

A PUBLIC inquiry of a somewhat far-reaching nature was held quite recently at Exeter before two Local Government Board inspectors. Owing, it appears, to an outbreak of enteric fever which occurred in Exeter and which was locally attributed to the consumption of cockles collected from near a sewer outfall, a representation was made to the Local Government Board by the Devonshire County Council, the Exeter corporation, and other local authorities, asking that the estuary of the Exe should be declared a "stream" within the meaning of the Rivers Pollution Acts, tidal estuaries being in the absence of such declaration outside the operation of those statutes. Much evidence was adduced in support of the application and we shall be interested to hear what view the Local Government Board takes of the matter. As far as we can gather from the

reports in the local papers the application was based almost solely upon danger to health through the consumption of polluted cockles and mussels, although certain other considerations such, for instance, as nuisance during bathing and boating, were brought forward in support of the scheme. There can, we think, be no doubt that danger must attend the consumption of raw shell-fish collected from near a sewer outfall, and this whether the outfall be into a tidal estuary or into the open sea, and there would appear to be reasonable ground for supposing that this danger must at least in some degree obtain even if the sewage be treated before discharge; in other words, it seems impossible to dispose of the risk altogether unless the collection of shell-fish from near sewer outfalls can be prohibited. Those who are familiar with our coasts know how luxuriant a growth of mussels may often be found around sewer outfalls, and how difficult, if not impossible, it is to prevent the public and the vendors of such molluscs from collecting them for consumption. The fact, however, that the danger cannot be entirely obviated is no justifiable reason for neglecting to minimise it, and the abstraction of sewage from our estuaries is certainly desirable upon æsthetic grounds if on no other. We can, however, conceive a position where the existence of a handful of cockles or periwinkles might lead to the expenditure of enormous sums of money in connexion with sewage disposal, and in a case such as that it might be questioned whether the public health could not be more profitably protected by the provision say, of a purer water-supply or of adequate isolation accommodation. Moreover, there arises here, as in the case of nearly all our food-supplies, the question as to how far we may be able to protect ourselves against polluted importations from abroad. It is perhaps not generally known that a very considerable amount of the supply of mussels to this country is derived from the Netherlands. Some control or at least inspection of these foreign sources of supply would seem to be indicated if we wish to place our shell-fish industry beyond reproach and to consume our molluscs with equanimity.

CANCER OF THE STOMACH IN THE YOUNG.

Dr. William Osler and Dr. Thomas McCrae have contributed to the *New York Medical Journal* of April 21st a valuable and exhaustive paper on this subject. A generation ago it was thought that cancer of the stomach could be left out of consideration in the diagnosis of obscure cases if the patient was under the age of 30 years. Unfortunately this is not true. In 3257 recorded cases the percentage of patients under 30 years of age is 2·5. In a series of 150 cases observed at the medical department of the Johns Hopkins University six of the patients were under the age of 30 years—i.e., 4 per cent.—an unusually high proportion. In childhood the disease is a pathological curiosity; there are only six cases on record in patients under 10 years of age. Between the ages of 10 and 20 years cancer of the stomach is also very rare; only 13 cases have been recorded. Between the ages of 20 and 30 years cases are more numerous. In the six cases above mentioned two features stand out prominently—an abrupt onset and an acute course. There was no loss of appetite in three cases, anorexia was present in two, and in one the state of the appetite was not noted. Pain was absent in only one case; in the others it was fairly severe. Vomiting was present in five cases; it was absent in the case where pain was absent. In four cases the duration was known; it was six months in two and four months in two. The following is one of the cases cited by the writers of the article. A man, aged 25 years, who had previously been well and strong, was admitted to hospital complaining of weakness and debility. Eight weeks before admission his friends noticed that he looked yellow. Two weeks later he had a slight feverish attack which kept him in bed for some days. The temperature did not rise above 102° F. He then lost his appetite and became wasted. There were occasional belching of gas and a bad taste in the mouth, but no nausea or vomiting. In the two weeks before admission he lost nearly 15 pounds. His physician discovered a mass in the abdomen and the patient therefore came to hospital. There were moderate pallor, sallowness, and emaciation. Below the ensiform cartilage was an elevation which descended with inspiration. The test-meal yielded 80 cubic centimetres of liquid which contained no hydrochloric acid and gave a reaction for lactic acid. Dr. Osler made this note: "The great mobility of the tumour with varying conditions of fulness and emptiness of the stomach seems very important. The anæmia, nausea, failure of stomach digestion, absence of free hydrochloric acid, and presence of lactic acid, in spite of the patient's age, point to cancer of the stomach." Exploratory laparotomy showed a firm mass near the pylorus of the size of an orange. Small nodules were felt on the posterior portion of the stomach. The patient recovered rapidly from the operation which seemed for a time to have a beneficial effect on the symptoms. He grew feebler and more emaciated, however, and died four months after the onset of symptoms.

SEPTIC SKIRTS.

THE streets and pavements of London are not kept as clean as they should be, and from time to time we have found occasion to direct the attention of some of the metropolitan vestries to their statutory duties in this respect. On the whole, the changes which have taken place in municipal cleanliness have been steadily for the better, but the improvements have been very slowly brought about, and they have not yet arrived at such a pitch of perfection that garments can be dragged on the pavement without becoming soiled. Nor does such an ideal state appear to be within the bounds of possibility. Automobile machines have not entirely replaced horses, and dogs are permitted not only to live, but to move about, in most parts of the metropolitan area, nor is it desirable or likely that either horses or dogs will be banished from London. It does not require any very prolonged observation on the habits of these animals to convince even a person of slow understanding that whilst animals are at large they are addicted to discharge excrement of fluid and of more or less solid character at not infrequent intervals. No means, as far as we are aware, have been suggested for the prevention of these nuisances, which we fear must be looked upon as the normal outcome of life as it at present exists. Another source of the pollution of the pavements results from the habit of expectoration which is practised among men, though less perhaps by Englishmen than by Americans and other foreign races. The habit is sufficiently prevalent to make the products of expectoration an easily recognised and general nuisance. It is one, also, for which the only apparent remedy is a change in the habits of the people and is distinctly not one for legislative interference. The habit of profuse expectoration is one also, it may be said, which had not merely the sanction but the distinct approval of one of the greatest of English physicians. Sir Thomas Watson was accustomed to stop and to expectorate freely in the streets of London whenever he detected a bad smell, and he explained that he considered the practice a valuable one for the prevention of ill effects from the source which produced the malodour. Many British workmen doubtless expectorate as a matter of habit rather than from any prophylactic theory, and perhaps habits have greater fixity of tenure than theories. Enough has been said to indicate the source and nature of some of the most prevalent of the nuisances of the streets and pavements, and it will be generally admitted that under the present conditions of life a certain amount of

such pollution must exist. It does not necessarily follow that this should be brought indoors. Unfortunately, at the present time a large number of women sweep the streets with the skirts of their gowns and other garments and bear with them wherever they go the abominable filth to which we have briefly alluded. Attempts are, indeed, often made by women to keep their dresses from dragging. Such attempts are usually unsuccessful. The management of a long gown is too difficult a matter for the majority of Englishwomen. The habit has arisen of seizing the upper part of the skirt and holding it in a bunch at a place called by women "the broad part of the back below the waist" and amongst anatomists by the less cumbrous term "gluteal region." This practice can be commended neither from a physiological nor from an artistic point of view. It is not to our purpose to descant on the absurdity or on the ugliness of the habit of walking in long skirts—these things are too palpable to be laboured; but we strongly protest from a sanitary point of view against the importation into private houses of skirts reeking with ordure, urine, and pathogenic microbes. For walking in the street a short skirt should be worn, and we commend the sensible walking gown now adopted by the best-dressed women to those whose business it is to write on the fashions in dress for women of the middle and lower classes.

AUTO-INTOXICATION.

DR. C. A. EWALD, in a recent number of the *Berliner Klinische Wochenschrift* (Feb. 12th, 1900), deals in a comprehensive manner with the subject of auto-intoxication as it occurs in various diseases and brings much of our scattered and fragmentary knowledge together. As examples of intestinal auto-intoxication he cites the nervous disturbances which occur in acute and chronic digestive disorders—for example, attacks of flushing and giddiness, headaches and curious sensations in the head, and throbbings and noises in the ears. Some cutaneous eruptions such as urticaria, acne, pruritis, and purpura are also due to intestinal auto-intoxication, and Müller and Manicatide have recently published instances of affections of the spinal cord in children resulting from the same cause. Periodic vomiting, asthma dyspepticum, tetany, and some of the anæmias are assignable to the same source. Among the auto-intoxications arising from diseased metabolism within the tissues and organs of the body may be included uræmia from renal disease, pancreatic diabetes, the cachexia resulting from cancer, Graves's disease, Addison's disease of the suprarenal bodies, myxœdema, cachexia strumipriva, cretinism, leukæmia, and pseudo-leukæmia. The eclampsia of pregnant women, gout, and migraine are attributable also to similar diseases of metabolism, giving rise to auto-intoxication with various chemical products. It is not, however, correct, says Dr. Ewald, to classify icterus gravis among the auto-intoxications, and the same may be said of acetonuria and oxaluria, which are symptoms of special diseases and which require treatment accordingly.

THE BIRTHDAY HONOURS.

WE regret that by an oversight the name of Lieutenant-Colonel Aylmer Martin Crofts, I.M.S., was not included in our reference to the honours bestowed upon members of the medical profession in the last issue of THE LANCET. Lieutenant-Colonel Aylmer Martin Crofts, who has received a Companionship of the Most Eminent Order of the Indian Empire, is residency surgeon at Gwalior and medical officer to the Maharajah. He served in the Afghan War of 1878-80 at Kandahar and with the Khyber Brigade, receiving the medal. In the Egyptian War of 1882 he was present at the battle of Tel-el-Kebir and for his services in this campaign received the medal and clasp and Khedive's Star. He was also with the Zhob Valley Expedition of 1884. A telegram to the *Times* through Reuter's Agency, dated Simla, May 22nd, states that "the Queen's birthday honours include 81 silver medals of the new Kaisar-i-Hind Order. 44 natives receive medals, which are given chiefly for services in connexion with the plague and famine." Among the European recipients are Captain John Grant (Medical Service) and Miss Charlotte Adams, Mrs. Henry Smith, and Miss Susan Campbell, lady doctors.

THE ROYAL ARMY MEDICAL CORPS STALL AT THE NATIONAL BAZAAR.

OWING to the untiring exertions of the ladies, married and single, who worked at the Royal Army Medical Corps stall its success was placed beyond doubt. During the days of sale the intake reached a sum close on £200. On the opening day H.R.H. the Princess of Wales visited the stall and purchased from amongst its exhibits. Her Royal Highness had also before the opening of the bazaar contributed some very valuable and pretty articles to the stall which found eager purchasers. The officers of the Corps express their indebtedness to the ladies who so largely contributed to the gratifying results we now announce.

NERVE STRUCTURE ELUCIDATED BY NERVE-STAINING.

IN giving an account of Mr. William H. Wynn's article on the Minute Structure of the Medullary Sheath of Nerve-fibres in THE LANCET of May 5th (p. 1297), we inadvertently omitted to mention that the modification of the Weigert-Pal process of staining the nerve tissue which was so effectively employed by Mr. Wynn in his reseaches was originally suggested by Dr. Joseph Shaw Bolton, now of the Pathological Laboratory, London County Lunatic Asylum, Claybury. An account of Dr. Bolton's method and of the steps by which he was led to it will be found in the *Journal of Anatomy and Physiology* for January, 1899, and for January, 1898. In the former article he called attention to the circumstance that the medullary sheath is deeply stained in parts of its circumference only, this occurring either as six sections separated by gaps or as six dots surrounding the axis cylinder, the outer part of the sheath being practically unstained. Mr. Wynn's article contained a more elaborate and amplified account of the structures seen and partially described by Dr. Bolton.

THE THIRTEENTH INTERNATIONAL MEDICAL CONGRESS: PARIS; 1900.

THE committee of organisation of this Congress has issued a circular reminding the members that the titles of communications must be received at the offices of the Congress, 21, rue de l'École de Médecine, before June 10th at the very latest, if they are to be entered on the official programme. The final prospectus is about to be issued and will contain the titles of all communications with the names of the authors which have been sent to the sectional secretaries in Paris in time. It is necessary, therefore, that all notices should be sent to Paris at once. The list of members of the Congress will be closed on July 15th, and communications can be made until that date, but such belated notices will not appear in the final prospectus. The British Government has officially appointed the following gentlemen to represent Great Britain and Ireland at the forthcoming Congress:—(1) Lieutenant-Colonel E. F. Drake-Brockman, I.M.S., delegate from the Indian Medical Service (Great Britain); (2) Brigade-Surgeon Lieutenant-Colonel Alexander Crombie, I.M.S., delegate from the Indian Medical Service (Great Britain); (3) Fleet-Surgeon Gilbert Kirker, R.N., representing the Naval Medical Service; and (4) Mr. Thomas

Joseph Stafford, F.R.C.S. Irel., Medical Commissioner of the Local Government Board (Ireland). These appear to be the only delegates of which the General Committee at Paris have official cognisance. Intending members of the Congress must send a visiting card, an intimation of the section they wish to join, and a post-office order for 25 francs to Dr. Duflocq, 21, rue de l'École de Médecine, Paris. Members of the Congress will receive without charge two sets of publications, the first at the opening of the Congress and the second at a later date. The first set will consist of—(1) summaries of the "reports" relating to the section which the member has joined; (2) an illustrated volume of 400 pages on French mineral waters and health resorts; (3) Medical Paris (a volume of about 400 pages); and (4) Guide Conty (a guide to Paris and the Exhibition). The second set will consist of three volumes relating to the subjects treated of at the Congress. Full accounts of the subjects that have come before the Congress will be published in 17 volumes of Transactions, the subscription price of which will be 50 francs, but which will be reduced to 45 francs for members. Members of the Congress are entitled to take part in the work of all the sections and in all the entertainments. They will also have free entry to the Exhibition during the sitting of the Congress (August 2nd to 9th), they will be presented with a badge, and will have a reduction of 50 per cent. on French railway fares. Rooms can be obtained through the following agencies, with which terms have been arranged by the committee, provided that the members make immediate personal application to the agencies. The Agence Desroches, 21, rue de Faubourg Montmartre, receives members at the railway station, conveys them to their place of residence, and on their departure conveys them to the railway station. Their charge for the first day is 20 francs, and for the last day 15 francs; for each intervening day 10 francs are charged for bedroom, lights, attendance, and early breakfast. The Agence des Voyages Pratiques, 9, rue de Rome, renders similar services at a charge of 6½ francs and upwards per day. This agency also provides sleeping accommodation at various prices, from 3 francs per day in dormitories to 5½ francs per day, and sets of furnished rooms, three or more, for 270 francs per month and upwards. The Agence des Voyages Modernes, 1, rue de l'Echelle, provides bedrooms from 6 francs per day, and board and lodging for 15 francs per day. The Agence Lubin, 36, Boulevard Haussmann, provides bedrooms for 12 francs per day for one person and 20 francs for two persons; the money must be paid in advance to the Crédit Lyonnais. The Société Française des Voyages Duchemin, 20, rue de Grammont, provides sleeping accommodation at charges of from 70 to 120 francs per week, and board and lodging at from 140 to 180 francs per week. By permission of the Minister of Public Instruction members of the Congress travelling alone can have sleeping accommodation in school dormitories for 5½ francs per day. Application should be made to the offices of the Congress, 21, rue de l'École de Médecine.

CAMBRIDGE SUMMER SCHOOL OF MEDICINE FOR QUALIFIED PRACTITIONERS.

A VALUABLE series of lectures and demonstrations to qualified medical practitioners will be delivered at Cambridge from June 25th to 30th. The proceedings will commence with dinner in hall at 7 P.M. on Monday, June 25th, followed at 8.30 P.M. by a reception in the hall of Trinity College by Professor Sir Michael Foster, M.P. On the succeeding days there will be cliniques at Addenbrooke's Hospital and demonstrations will be given in the Pathological Laboratory, the subjects of demonstration as at present arranged being Malaria on June 26th, by Dr. Nuttall; Tuberculosis on June 28th, by Professor Sims Woodhead; Antitoxin on June 29th, by Dr. Louis Cobbett; and Blood on June 30th, by Mr. Strangeways Pigg. Demonstrations will also be given in the Pharmacological Laboratory by Dr. Dixon and in the Physiological Laboratory by Dr. Shore and Dr. Hopkins. Lectures will be delivered on the Fracture of Bones, by Dr. J. Griffiths; on Angina Pectoris, by Professor Allbutt; on the Vermiform Appendix, by Dr. Rogers; on the Factors which Determine Climate, by Mr. Yule Oldham; on Specimens Preserved in Formalin, by Mr. Strangeways Pigg; and on Public Health, by Dr. B. Anningson. Breakfast, lunch, and dinner will be taken in hall each day. On June 27th Professor Allbutt will give a garden party, and on June 29th there will be a smoking concert in King's College Hall. It is hoped that the visitors in order of application will be accommodated in the colleges; the inclusive fee is four guineas. Applications should be addressed to the honorary secretary, Dr. Joseph Griffiths, Medical Schools, Cambridge. The opportunities offered by this invitation, which is a repetition of that given in 1895, are well worthy of attention, glimpses of life in a famous university town being combined with post-graduate instruction by eminent teachers.

PERNICIOUS ANÆMIA AND ITS PATHOLOGY.

DR. RICHARD S. CABOT of Boston, well known for his excellent work on the "Clinical Examination of Blood," read an important paper on the above subject at the recent annual meeting of American physicians, held at Washington (May 1st, 2nd, and 3rd). The conclusions arrived at by him were based on a study of 110 cases of pernicious anæmia. Of the 110 cases reported 57 were males and 53 were females. Of the cases occurring in females four followed parturition and in one of these in which a necropsy was held there were leucocytosis and diphtheritic endometritis. Dr. Cabot finds that the disease is generally one of middle life. He had seen all the cases within seven years. Many of the patients were at first thought to be suffering from tuberculosis and 14 cases occurred at about the time of the menopause. Hæmorrhage is probably a symptom and not a cause of the disease, and it has been observed from the bowels, the stomach, the nose, the gums, and the ears. The symptoms are constant, though in certain cases they are very mild. It is not the lack of red blood corpuscles only that causes the symptoms. Muscular weakness, dyspnœa, and gastro-intestinal symptoms, such as vomiting and diarrhœa, are seen, and the latter train of symptoms may be often paroxysmal. The theory that atrophy of the gastric glands is a cause of the disease cannot be maintained. Hæmic cardiac murmurs are always heard and occasionally a true regurgitant (mitral) murmur is detected. The liver was found enlarged in 30 cases, the spleen in 13 cases. There were hæmorrhages into the retina in 36 cases, and in 15 cases the fundi were normal. In exactly two-thirds of the cases fever was present, the temperature varying from 99° to 100° F. The urine was normal in 53 cases. In other cases albumin and hyalin or granular casts were present. The urine was usually pale. There were nervous symptoms in one-third of the cases, and it is probable that obscure nervous lesions were really present in a larger proportion. In 106 cases the red blood corpuscles were below 2,000,000 per cubic millimetre, and in four cases they were above that figure. The leucocytes in 72 cases were below 5000 per cubic millimetre, and in 38 cases they were above that figure. The hæmoglobin in 79 cases was high and in 81 cases it was normal or low. The red corpuscles were usually enlarged and such enlarged cells were found at one time or another in 107 cases. The lymphocytes were normal in number, the polymorphonuclear leucocytes were decreased, and myelocytes were frequently present. The symptomatology and course of the disease were quite unlike

those of secondary anæmia. No case recovered, though in 69 cases one or more remissions were seen. 20 cases were progressive. In 78 cases the duration of the disease was from one to three years. Treatment was negative, arsenic and bone-marrow had no effect, but in some cases laxative treatment seemed to have done some good. This seems to bear out Dr. W. Hunter's idea that the disease is a toxæmia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

IN addition to those whose names we have already given, we understand that Mr. Pearce Gould, Dr. J. Ward Cousins of Portsmouth, and Mr. Jordan Lloyd of Birmingham will be candidates for the vacancies upon the Council of the Royal College of Surgeons of England.

HOUSES LET IN LODGINGS.

A CASE of much importance in connexion with the sanitary administration of London was heard last week by Mr. Slade at the Southwark Police-court. Experience of this administration has increasingly shown that the most effectual method of maintaining the houses occupied by the poor in proper sanitary condition and of the prevention of overcrowding is the regulation of houses let in lodgings. This regulation, indeed, is often an absolute necessity, and especially in the central districts where landlords are able more largely than in other districts to trade upon the necessities of the poor. The regulation of such houses not only controls the landlord but also the tenant who is expected to coöperate in the maintenance of cleanliness and proper ventilation of the rooms. The enforcement of the by-laws has served a useful purpose in those districts where the work has been undertaken, and the London County Council have persistently urged upon the authorities of other districts the adoption of a like course. The question has from time to time arisen as to what is a house let in lodgings. There has been no doubt that the ordinary tenement house which was originally constructed for one family but which has come to be occupied by several families, often a family in every one or two rooms, is within this definition. Where there has been doubt is in the case of blocks of artisans' dwellings where each suite of two or three rooms may claim to be a separate house. The case to which we refer is likely to have a considerable influence in determining how far blocks of artisans' dwellings are for the purposes of the Public Health Act to be deemed to be houses let in lodgings. The Gun-street dwellings in the parish of St. George the Martyr, the subject of the proceedings before the Southwark magistrate, have previously been a cause of anxiety to the sanitary authority and on the recommendation of Dr. F. J. Waldo, the medical officer of health, numerous rooms have been closed as unfit for human habitation. Repairs have been effected, alterations made, and the rooms re-let, but while improvements have been made in the buildings the inhabitants remaining have been, to use the words of the vestry clerk, persons who were often uncleanly in their habits and whom it was essential that the sanitary authority should supervise. The vestry, therefore, acting on the advice of their medical officer of health, have wisely determined to bring these premises under regulation, and there seemed reasonable prospect that this could be successfully done because the tenements are not such as are known as "self-contained," but the sanitary appliances on each floor were outside the dwellings and were used in common by the tenants. The contention of the vestry that each block was a separate house and that the rooms were lodgings was strongly contested by the owner who quoted a number of cases ranging from the time of Charles I. and urged that the registration law embodied in those cases must be regarded as safeguarding the interests of the inmates who would be disenfranchised if they were to be deemed to be lodgers. Mr. Slade decided against the vestry on the ground that the landlord did not reside on the premises and did not exercise any control over them either by himself or his servants, and therefore that the tenements could not be regarded as lodgings. It will be seen that Mr. Slade's decision is capable of much wider application than to blocks of artisans' dwellings and that if sustained it may affect the regulation of much tenemented property of a higher class. The vestry have appealed and it is to be sincerely hoped that this appeal will be successful and that it will be found that the definition of a lodger for the purposes of the public health law is entirely different from that for the purposes of the registration law. It is, indeed, difficult to believe that this will not be the result, for it would otherwise always be possible for an Act of Parliament dealing with one subject in effect to repeal another Act dealing with an entirely different subject which was not under consideration at the time the subsequent Act was passed. We shall await the final decision with much interest.

THE SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.

THE annual meeting of the council of the Society for the Prevention of Cruelty to Children was held on May 15th under the presidency of Mr. W. H. Collingridge. The chairman was able to give the satisfactory information that notwithstanding a generally prevalent demand for war funds the income of the society during the past year showed an increase of £1000. This gain, moreover, had resulted from an influx of ordinary subscriptions. On the other hand, a deficit of £7700 on account of expenses had to be met. This amount was covered by reserve funds. Among other business transacted at the meeting was the passing of a resolution in support of Lord James's Juvenile Offender's Bill. It was also decided to petition Parliament for the addition to the Bill of a clause requiring the presence of a medical practitioner during the infliction of corporal punishment. Such an arrangement ought to strengthen the measure, and if sensibly carried out should not impair its punitive effect. Another resolution strongly supported the Bill forbidding the sale of intoxicating liquors to children. It is instructive to note that this resolution was approved by representatives from widely separated parts of England and from Ireland, and evidence was given proving that the proposed legislation is much desired by the working classes in the north.

PILOCARPINE AND WILLOW-BARK.

SOME excellent work is evidently being done in the Wellcome Chemical Research Laboratories judging from the important contributions published from time to time in the Transactions of the Chemical Society. This kind of work should receive every encouragement, since it is devoted to the throwing of further light upon the pharmacology of the materia medica. We are glad to see that these communications as they appear from time to time are being published in separate pamphlet form. Not very long ago we received an interesting paper of this kind on some gold salts of hyoscine, hyoscyamine, and atropine by H. A. D. Jowett, D.Sc., and more recently we have received two further papers on the substances quoted in the title of this annotation. For some time considerable obscurity has surrounded the nature of pilocarpine and the number and kind of specific alkaloids contained in jaborandi leaves. Although the experiments are still in progress some interesting results have been obtained. A base, for instance, isomeric with pilocarpine, is produced from it by the action of heat or alkali and it is

proposed to call it isopilocarpine. This substance has been found in jaborandi leaves. Pilocarpidine appears, however, not to be present in ordinary jaborandi leaves, but in the jaborine of Harnack pilocarpidine as well as isopilocarpine are found. As to the physiological experiments on isopilocarpine, pilocarpine, and pilocarpidine, Professor Marshall of University College, Dundee, reports that the substances produce similar effects on the secretory activity of the sweat and salivary glands, pilocarpine being much the most powerful. Isopilocarpine is comparatively less depressant to the hearts of rabbits but not to those of cats and men. The jaborine prepared by Merck possesses a mild pilocarpine effect. Dr. Jowett has also turned his attention to the chemistry of willow-bark with the result that he has succeeded in recognising and separating a new glucoside for which he proposes provisionally the name of "salinigrin." The yield of this crystalline glucoside is about 1 per cent. of the bark. It yields on hydrolysis a dextro-rotatory sugar which gives qualitative reactions analogous with glucose. At the same time hydrolysis produces metahydroxybenzaldehyde which may be easily distinguished from salicin by the fact that sulphuric acid produces no change of colour whilst with this reagent salicin yields a blood-red colour. This is the sort of work which is calculated to throw a much desired light on the action of various drugs and their principles and it is an encouraging sign of the times that such important work is undertaken by manufacturing chemists.

MILITARY DRILL IN SCHOOLS.

WE are pleased to see that Lord Balfour's useful suggestions with regard to physical training in schools [1] have not been forgotten. Very similar in its purport is a scheme recently introduced at Macclesfield. A Patriotic Association has been formed in that city for the encouragement of physical exercise and military drill among boys from 10 to 17 years of age. The course will begin in the elementary day schools and will be carried out in them, or in a Volunteer drill hall where the school playground is too small, under the supervision of a qualified drill inspector. The boys will also be enrolled in cadet corps and taught to handle a rifle, with a view to their enrolment later in rifle volunteer regiments. This plan ought to work well. It is practical, it is adequate without being too ambitious, it ought not to prove expensive or to interfere with the ordinary school work, it is free from sensationalism (one great pitfall of the times), and finally it has a definite end in view. It thus promises to fulfil very successfully the purposes of Lord Balfour's proposal to which it evidently owes its inspiration. As an example of public spirit judiciously applied we commend this scheme to the attention of all who are concerned with school education.

THE QUESTION OF HORSE AMBULANCES.

IN THE LANCET of Dec. 9th, 1899, p. 1599, appeared a leading article calling attention to the inadequate provision for dealing promptly with the accidents which daily occur in our large metropolis and suggesting some remedial measures. Our first suggestion and the one that we considered to be the most important was the maintenance of horse ambulance wagons at hospitals, and although it still remains a blot upon our great city that in this respect we are far behind some of the large towns in America, and at least one town in Ireland, it is gratifying to learn that Manchester has taken steps towards the establishment of a similar ambulance service to that which we advocated for London. On Thursday, May 24th, a deputation from the Medical Charities Committee of that city attended a meeting of the Watch Committee of the Manchester Corporation and laid before the committee reasons for the provision of horse ambulances, Mr. Alfred Simpson, chairman of the House Committee of the Royal Infirmary, remarking that the provision of proper ambulance facilities had long engaged the attention of the medical authorities. In the beginning of the year, on the advice of Professor D. J. Leech, the matter was brought before the members of the Red Cross Society and a resolution was passed inviting the municipal authorities to provide horse ambulances. This resolution has received the endorsement of the Sanitary Association of Manchester and Salford. Mr. Alderman Rawson, the chairman of the Watch Committee, assured the members of the deputation that his committee were in sympathy with their object. A special sub-committee had already under consideration the whole question of the provision of horse ambulances in Manchester. Surely what is necessary for Manchester is necessary for London with a population ten times larger. How long shall we be put to shame in the cause of humanity by our sister city?

[1] THE LANCET, Feb. 10th, 1900, p. 398.

THE AUSTRO-HUNGARIAN WAR OF 1848-1849 AND THE BOER WAR: A CONTRAST.

A COMPARISON has been frequently instituted between the situation of the Boers in the present war and that of the Hungarian revolutionary army prior to the capitulation of Vilagos in August, 1849. As the circumstances are not parallel, however, any conclusions drawn from such a comparison are not only altogether misleading as to the causes which were operative in the two cases but unjust as to the motives and conduct of the Hungarians who were disinterested patriots fighting in defence of freedom, justice, and independence. Kossuth and Görgey did not enrich themselves, they had not sought to oppress anyone, nor had they been opposed to any system granting an equality of political rights to all—quite the contrary. Some of the facts and incidents connected with the campaign of the Hungarian army in 1848-49 are historically of a highly interesting and romantic character. It may not be generally known that Surgeon-Major Theodore Duka, a retired officer of the Indian Medical Service who has been long resident in London, and Count Julius Andrassy were attached to the staff of the Commander-in-Chief, General Görgey, and took a prominent part in the war. Surgeon-Major Duka—then a first lieutenant and adjutant in the Hungarian army—at the battle of Komorn with the Austrian army on April 26th, 1849, having rendered conspicuous services in rallying some of the Hungarian troops, was decorated with others with the Order of Valour, Class III., in the presence of the Hungarian forces paraded for the purpose by General Görgey in obedience to his general order. That Görgey displayed remarkable ability as a general and was a man of great enterprise and courage goes without saying, seeing that the Hungarian army whilst under his command achieved some brilliant victories and for a long time kept the whole Austrian army at bay; but he was really more than this, for, when Russia threw an overwhelming force into the field and success was no longer possible for the Hungarians, Görgey with patriotic wisdom and courage capitulated in order to avoid an inevitable and purposeless sacrifice of life. The breach which had already taken place between Kossuth and Görgey widened still further and Görgey by his action on this occasion covered himself with unmerited obloquy. But time ultimately brought its recompense and reward, for it was recognised on all sides that Görgey was right and had acted with great wisdom and self-abnegation in what he had done. After the capitulation of Vilagos in August, 1849, Andrassy and Duka

had to flee; they came to this country and had to bear their exile, misfortunes, and straitened circumstances with what fortitude they could. Captain Duka, as he was then, was still a young man; with indomitable energy he learnt the English language and elected to enter the medical profession, and for that purpose became a student at St. George's Hospital, and, having qualified, he passed into the Indian Medical Service from which, after having been present through the Mutiny, he retired many years ago. He took up his residence in his adopted country where he has since had the gratification of entertaining his old general as his guest. Count Andrassy in the meantime had become Prime Minister of Hungary in 1867 on the restoration of the constitution of 1848 and the reorganisation of the Austro-Hungarian Empire. After having been sentenced to death and hanged in effigy with the defeated Hungarian generals, who were actually executed and not in effigy merely, Andrassy had subsequently the privilege of being the official medium for placing the crown of St. Stephen on the head of Francis Joseph as King of Hungary. Time brings great changes on his wings and no ruler is more deservedly popular and beloved than is the Emperor Francis Joseph by his Hungarian subjects at the present time. Surgeon-Major Duka is now one of the governors of the hospital (St. George's) where he was once a student.

THE STUDY OF CHILDREN'S DISEASES.

A MOVEMENT is in progress for the formation of a society devoted exclusively to the study of children's diseases, and a meeting of the supporters of the proposal will be held at 5.30 P.M. on Monday, June 11th, at 20, Hanover-square, W. A circular to this effect has been forwarded to the members of the staffs of the different hospitals for children throughout the country, as well as to the members of the Medical Officers of Schools Association. We understand that the project, so far, has received a liberal measure of approval from those likely to be interested.

"MR. VICTOR HORSLEY AND THE MEDICAL ACTS."

WE have received the following letter from Mr. Victor Horsley:—

To the Editors of THE LANCET.

25, Cavendish-square, London, W., May 30th, 1900.

DEAR SIRS,—My attention has been drawn to the fact that in the last issue but one and the present issue of THE LANCET you make certain statements with regard to my speech at the Manchester Conference calculated to convey the idea that my interpretation of the Medical Acts is erroneous; and, furthermore, you place these statements prominently in your columns of annotations. I note that although you head your second annotation with my name you simply publish a letter from some person not in the profession and say you are not called upon to make any remark upon it. As that letter contains a complete misrepresentation of the administration of the Medical Acts by the General Medical Council I think it was your duty as the editors of the leading medical journal to point out the bearing of the Medical Acts on the subject. The obviousness of this will be seen from the fact that at present you have only published one side of the matter and that a misleading one. The Medical Act provides, Sections 28 and 29, two different methods of procedure whereby the General Medical Council is empowered to erase from the Register the name of a practitioner who has been guilty of an offence against the ethics of the profession, such as is defined in Section 29 as being "conduct infamous in a professional respect." These two methods of procedure are as follows, and the first is conditioned by the fact that various medical corporations possess under their charters disciplinary powers. Under Section 28 the Medical Act provides, if a medical corporation examines into the ethical conduct of a practitioner and convicts him, that on such conviction being reported to the General Medical Council, the Council need not put the profession to the expense and trouble of holding a second inquiry, but may, if they see fit, accept the judgment of the corporate body and may forthwith erase the name of the person convicted from the Register. This was the method by which Mr. Alabone's name was erased from the Medical Register. The second procedure is that whereby the Council holds the inquiry itself and if they find the person guilty they erase his name under Section 29 of the Medical Act. My statement at Manchester, therefore, is perfectly true and I protest against your publishing statements respecting the Medical Acts which, if unaccompanied by explanatory correction, are extremely misleading. Further, as you have thought it right to particularise myself in this matter I must ask that you give this letter the same publicity that you have to other statements in your annotations.

Yours faithfully,

VICTOR HORSLEY.

We made no comment upon the letter in question from Mr. Alabone Cheverton because we conceived that everyone knew the position. Clause 28 of the Medical Act, 21 & 22 Victoria, cap. 90, says nothing about the examination into ethical conduct but merely says: "If any of the said Colleges or the said Bodies at any time exercise any power they possess by Law of striking off from the List of such College or Body the Name of any one of their Members, such College or Body shall signify to the General Council the Name of the Member so struck off; and the General Council may, if they see fit, direct the Registrar to erase forthwith from the Register the Qualification derived from such College or Body in respect of which such Member was registered." There is nothing in this clause about "infamous conduct in any professional respect"; that expression is contained in the next clause under which Mr. Alabone was *not* struck off from the Register. We do not understand that Mr. Horsley accuses us of incorrectly reporting and it appears that he has been inaccurate.

INAUGURAL ADDRESS BEFORE THE AMERICAN NEUROLOGICAL ASSOCIATION, 1900.

IN the inaugural address[1] delivered by Dr. Edward D. Fisher, the President, for the present year it is pointed out that the position of neurology among the divisions of medicine and surgery has changed very much in the last 20 or 25 years. "Perhaps no special branch of medicine," continues Dr. Fisher, "comes into quite so close touch with general medicine and medical surgery as neurology." While a high level of work had been achieved in this field it had also been sedulously exploited by the charlatan. The clinics held in the Old World in Paris, Vienna, Berlin, and London had made these places centres of worldwide neurological fame, and eventually it had come to dawn on the professional mind that a full and thorough course in psychiatry and neurology was a paramount necessity. The speciality of neurology should never remain narrow and be separated from general medicine. The heart, lungs, and viscera had to be carefully explored in nervous as in other diseases. A special illustration of this was seen in syphilis which had such well-defined effects upon the viscera and on the nervous system. Therapeutics should receive more attention in the future than in the past; diagnosis and localisation of the disease did not complete the neurologist's work. Scientific training and investigation would lead the way to means of treatment, and the fact that Dr. Weir-Mitchell's methods had been thus discovered made it certain that more might be expected in this direction from American neurology. Dr. Fisher concluded by saying that "the note of warning I would sound to those about to enter this field of medicine is to keep up as broad a knowledge of all medicine as possible. No one should enter neurology as a speciality without having first had an experience in general

[1] Journal of Nervous and Mental Diseases, May, 1900.

practice. I believe, if I read the signs of the times aright, that is the tendency of the neurology of the future."

THE CROONIAN LECTURES FOR 1900.

THE Croonian Lectures for 1900 will be delivered by Dr. F. W. Mott, F.R.S., before the Royal College of Physicians of London at the College, Pall Mall East, on the following dates: June 19th, 21st, 26th, and 28th. The subject is "The Degeneration of the Neurone," and the lectures will commence at 5 P.M.

A COMMITTEE, of which the Prince of Wales is chairman, has been formed for the purpose of providing a memorial to the late Duke of Westminster. The late duke, as our readers know, always took the deepest interest in all that concerned the poor, and hospitals and nursing necessarily formed part of that interest. The suggestion that the memorial shall be in the form of stained-glass windows for the Abbey which takes its name from the city of which the late duke was Lord High Steward is a good one, and the fund will no doubt be freely supported. The Duke of York is treasurer to the fund, but subscriptions should be sent to the honorary secretaries, 1, Great George-street, Westminster, or to the Bank of England.

IT is announced that the lepers on Robben Island have collected a second sum of money for the African wounded soldiers' fund with the object of showing their appreciation of the benefits conferred upon them by the British Government. The pathos of this act cannot fail to appeal to the medical profession.

Mr. H. T. Butlin, D.C.L., will deliver the Cavendish Lecture of the West London Medico-Chirurgical Society at 8.30 P.M. on Friday, June 22nd, in the Town Hall, Hammersmith. He will take as his subject the Application of Pathology to Surgery.

THE honorary freedom of the Salters' Company will be conferred on Sir William Mac Cormac at Salters' Hall on Monday, June 18th.

THE WAR IN SOUTH AFRICA.

EVENTS have proceeded with dramatic rapidity at the theatre of war in South Africa. Lord Roberts's converging forces—a large crescent-shaped wave overlapping and enveloping opposition by its horns and overcoming all resistance by the driving power of its centre—have moved on a concerted plan with extraordinary rapidity, and the British flag will soon fly over Pretoria and Johannesberg. We, in common with other journals having direct information from the seat of operations, conjectured some time ago that the resistance offered by Boer forces might collapse at any moment, but we did not realise that the fortunate occurrence was so near or that the news from the seat of war would from day to day tell one story—that of the hasty retreat of the enemy from one defensible position after another. Such, however, has happened, and now, for practical purposes, the war is over.

While the Boers have shown themselves, whether upon their own initiative or upon that of foreign allies, to be good tacticians, and while they have exhibited an alacrity which almost amounted to genius in seizing upon positions best adapted to their methods of warfare, their weakness has been apparent in their want of any bold and original strategy. As soon as our generals had mastered the situation and had a sufficient number of men at their disposal to carry out their designs the whole aspect and character of the war changed and a series of "entanglements," any one of which contained its promise of tragedy, resolved itself into a resistless march to victory.

The *Times* correspondent in describing the military situation in a communication which appeared in that journal on May 28th alluded to the death-rate in the hospitals at Bloemfontein as being very high. This is not surprising. The Free State capital is about 4600 feet above the sea level, and the diurnal variation of temperature at this altitude must tell heavily on sick men, and we agree with the writer in thinking that efforts should be made to remove invalids from Bloemfontein to a more equable climate. The Portland Hospital is, however, working well at Bloemfontein.

We have more than once called attention to the admirable services rendered by the Indian coolies and dhoolie-bearers during the present war and have expressed a hope that their work would be requited by something more tangible than mere praise. We were, therefore, glad to notice that Sir George White, on the occasion of his being presented with an address and service of plate from his fellow Ulstermen in commemoration of his defence of Ladysmith, earnestly commended the case of the Indian coolies to consideration in the following words: "These men, who discharged most valuable duty during the siege of Ladysmith, are now drawing pay at Indian rates, which placed them on inferior terms to the soldiers with whom they were serving and inferior to those which they would be enjoying in their own country." This is a matter which should be set right generously and promptly. The war will entail, we know, an enormous amount of departmental work, but we trust that the modest claims of the dhoolie-bearers will not be overlooked in the apportionment of rewards in more obvious directions.

We direct the attention of our readers to the sketches of the Boer trenches at page 1609, which we owe to the courtesy of Mr. Clinton Dent and Messrs. George Bell and Sons. They enable us to realise far better than any description would do the serious nature of the difficulties which our troops had to encounter in the direct attacks on Boer positions which they were in some cases, if not in all, compelled to make.

THE IMPERIAL YEOMANRY HOSPITAL.

BY ALFRED D. FRIPP, M.S., F.R.C.S.

A patient came into the Imperial Yeomanry Hospital with a perforating bullet wound which entered just outside the right angle of the mouth and emerged beside the second dorsal spine two inches to the right from the middle line. The body of the mandible had been splintered just below. The splintering included the sockets of the three molars, and an immediate operation was called for to remove the loose splinters of tooth and bone which had already caused an abscess in the cheek. But the interesting part of his case lay in injuries that had been inflicted on the brachial plexus. Firstly, the eyeball was retracted and the palpebral fissure diminished, and the pupil was very small and dilated neither to shade nor to painful impression on the right side of the neck. Possibly this total paralysis is due to the injury to the cervical sympathetic chain, but since no other structure of the carotid sheath appears to have been damaged it seems more probable that it is due to damage to the ramus communicans of the first and perhaps also the second dorsal root. True, the track of the bullet does not seem to have been close enough to the middle line to hit these rami communicantes, but it is not outside the range of probability that they could have been caused by concussion or hæmorrhage. He has been under observation here for about a month without showing any sign of diminution of the sympathetic paralysis, and nerve lesions, if they are going to clear up, as they frequently do to an altogether astonishing degree when they are due to concussion or hæmorrhage, generally do so long before that period. Secondly, on admission he was found to have complete paralysis of all muscles of the right arm, including the deltoid, the pectorals, and the serratus magnus and the muscles below them. The skin sensations were unimpaired down to the insertion of the deltoid. Below that there was universal hyperæsthesia. This hyperæsthesia has steadily diminished and has given place to normal sensation, until now, five weeks after the receipt of the wound, it is limited to an area about one and a half inches wide extending along the outer border of the forearm and arm from two inches above the elbow-joint to the wrist-joint. Accurately at the wrist-joint the hyperæsthetic area just described is almost isolated from the second hyperæsthetic area which embraces the entire thumb and just the radial side of the index finger down to the first inter-phalangeal joint. Thus apparently the whole of the roots of the brachial plexus were involved, though the lesion was probably not an irrecoverable one, for the two areas still remaining hyperæsthetic are those supplied by the fifth and sixth roots, and it must have been the first dorsal

root which was damaged if, as seems likely, the sympathetic paralysis was not due to a division of the cervical sympathetic cord.

It is by no means uncommon in our experience for a bullet to be found with its wrong end foremost, so to speak, and this even at the very end of a long track which appears to have been inflicted by a direct, not ricochet, shot. Sometimes, but not always, a possible explanation of the turning of the bullet has been given by the fact that it has touched a bone in its course.

Complete transverse penetration of the head or face is by no means rare, and, as in penetrating wounds in other parts of the body, it is often astonishing what slight damage has been done. In one case the bullet entered just upon the external auditory meatus on the right side and emerged through the external angular process of the frontal bone on the left side. The patient was absolutely blind in the left eye and the retina was one mass of hæmorrhage. Despite the violently septic character of the entrance wound on admission the man is now making excellent progress in every respect and presents about the best instance we have had of the extraordinary way in which nerves will recover which apparently were completely shattered. The second and the third divisions of the fifth nerve on the right-hand side were completely paralysed both as to motion and sensation. The ocular muscles of the right-hand side were paralytic, but they, too, have recovered, and even the optic nerve, which was so much damaged as to cause very well-marked optic neuritis, is also recovering.

We have had quite a large number of bad cases of hæmorrhoids. Whether they are caused by riding—for almost all the patients have been mounted troops—or by the unnatural stress upon the rectal eliminating apparatus we are not sure, but it is a fact that most people's alimentary canal in these parts varies in a most unaccountable manner between the states of diarrhœa and intestinal obstruction.

A young officer came into this hospital the other day with eight wounds. One bullet had perforated his lumbar region and another had perforated his thigh. In neither case did any harm result. A piece of shell had blown a piece out of the inner aspect of both thighs and three pieces off the bottom of his scrotum, while a third bullet had lodged in the cruro-scrotal fold, whence it dropped out as he was standing up to be examined. He has left the hospital in no way the worse, apparently, for his narrow escapes. Another most extraordinary case was that of a man in whom a bullet entered the right thigh on the inner aspect about two inches below the cruro-scrotal fold. The leg was skiagraphed, but nothing could be seen of the bullet. An abscess developed in the other thigh at about a symmetrical position to the entrance wound. It was incised and the bullet was found, and the finger could then retrace the track of the bullet across the front of the bodies of the two pubic bones to the wound of entrance.

A man was shot while his right hand was hanging in front of his abdomen, the bullet tunnelling the radius without doing any harm, and then piercing the abdominal wall two inches above the middle of Poupart's ligament it emerged through the middle of the dorsum ilii. When admitted into the hospital he presented no abdominal symptoms whatever, but we kept him in bed and on restricted diet so as to be on the safe side, for I had seen at Wynberg a similar case in which a couple of weeks after the receipt of the wound a hard tender swelling developed in the right iliac fossa, which, as there was considerable pyrexia, was taken to be an abscess. It was incised and proved to be a large hæmatoma. Our patient also was not long before he developed a swelling in the cæcal region. This swelling was neither tender nor painful, nor was his alimentary canal in any way upset. He developed a high temperature every night, but we had great difficulty in persuading him that he was ill and in getting him to let us do anything. On incision the swelling proved to be a huge fæcal abscess, and for two days all his fæces poured out through the incision. This distressing symptom suddenly ceased and the wound proceeded straight away to heal up in a most rapid and satisfactory manner. We have had three or four other instances of perforations through the iliac and cæcal region that have presented no symptoms at all. In another case the man was shot through the pelvic bones lower down; the entrance wound was behind, just two inches below the posterior superior spine and two inches to the left of the middle line, and the exit wound was just to the right of the middle line in front under or through the edge of the descending ramus of the pubes. There was no sign whatever of damage to the bones, the alimentary canal, the blood-vessels, the peritoneum, or the bladder, but only sufficient damage to the cords of the sacral plexus to cause paresis of the gastrocnemii, and an area of anæsthesia over the heel indicates, I take it, damage to the first sacral nerve. The anæsthetic area shortly became hyperæsthetic and is now rapidly returning to normal.

Even before we left England such a large number of perforating wounds of the trunk and head, to say nothing of the limbs, without any permanent damage had been recorded in the medical journals that I take it that you have no desire to hear repeated again all these miracles. Every train-load brings us fresh instances of them. In the last, for instance, was a man in whom the bullet entered behind the middle of one clavicle and emerged through the opposite groin. One thing which I have not seen noted in the medical journals, but which is being borne in upon us more and more, is the rapidity with which the effects of general anæsthetics pass off in this climate. Perhaps it is due to the skill of our anæsthetists, but the fact remains that it is much rarer to see any vomiting or nausea after operations out here than it is at home, and the rule is to find the patient so well that within an hour of his being put back to bed he is asking to be allowed to smoke or even to get up.

Deelfontein, May 7th.

THE CHARING-CROSS HOSPITAL EXHIBITS AT EARL'S COURT.

THE Appeal Committee of Charing-cross Hospital have organised an interesting exhibit at the entrance of the Old English Village which is one of the most attractive features of the Woman's Exhibition held this year at Earl's Court. Outside there are tents fitted up for field ambulance work and dummy figures representing wounded soldiers so as to illustrate the ingenious devices by which dressings and splints are extemporised out of anything that may be found on the battle-field, from a broken rifle to the bark of a tree. Within the building there are several compartments, the largest being a surgical ward with eight beds differing in structure and suited for various special purposes. Thus one bed is provided with electric light so as to facilitate examinations with the ophthalmoscope, while a system of rubber tubes enables water to circulate round the head of the patient and thus replaces the more clumsy ice-bag. The Gorham bed attracts much attention. With no great muscular effort, but by merely turning a small wheel, the patient may be raised in almost any position or lifted several inches above the mattress while the sheets are being changed, the body being suspended on canvas bands stretched across a moveable iron framework. Other beds are provided with special apparatus for fractured thighs and legs, and for abdominal injuries, &c. The combined bed-table and locker used is also very ingenious. These beds stand on Messrs. Geary, Walker, and Co's. patent anhydrous flooring. An asphalt foundation is laid first, then a thin layer of wood, and on this are placed oak blocks. Between the blocks a thin partition of an asphalt composition is sufficiently elastic to allow for expansion and thus the risk of cracks or of bulging is met. In the centre a Pridgin Teale fireplace ensures a more perfect consumption of coal, consequently producing more heat, less smoke, and not requiring so much attention as is usually the case. The fan windows devised by Mr. Robert Adams should be carefully examined. Instead of the ugly side projections to which architects so strongly object, when the top of the window is made to open inwards the side draws out a light metallic fan which when unfolded prevents the air escaping otherwise than from the top. Thus directed it must strike the ceiling, whence it is diffused over the ward without causing any sharp draughts. Apart from this the large window-panes can be raised by merely removing a small bolt and then twisted right round by means of a central pivot. Thus the external surface of the glass can be brought inside and cleaned This contrivance would be just as useful in private houses as in hospitals and would put an end to the difficulty and danger of window-cleaning. Messrs. Burroughs and Wellcome exhibit a ward medicine case, not unlike a brief bag, which contains a variety of useful things in a small compass.

Next to the ward there is a model operating-room. In the centre to give a good light the wall and ceiling on the northern side are of ground glass. Between this ground glass and a second outer and plain glass covering built for protection there is an electric heating apparatus. This is important, as otherwise the wide glass expanse would chill the air of the operating-room. Inside there are hot-air coils and ventilators. Needless to say, that all surfaces are absolutely smooth and air-tight and that there are no corners or ledges. The water for sterilising the instruments is heated by electricity at a cost of less than a penny per hour. Mr. George B. Davis, sanitary engineer, provides the closets, the baths, and a running-stream lavatory for the operating surgeons, with a shampoo for sluicing the arms. The ledges of this and other lavatories and sinks all slant towards the basins, so that no water or soapsuds can stagnate on the borders. Glass, gun metal, and enamelled hardware alone are employed, and the connexions with the piping are not soldered but established by means of "union" screws, so that the lavatory can be readily removed to any other place. Underneath the waste water discharges into an open channel and the connexion of this channel with the drain-pipe can be plugged up and completely cut off. For the bath, which is in another room, the water enters all round the sides from the rim, so that the bath can be washed out before it is used. The delivery is so abundant that the bath can be filled in three-quarters of a minute and it can also be emptied with equal promptitude. All the fittings are of good gun-metal, and the towel-horse being of hot-water tubing the linen is duly heated and kept warm. At the sink the grid is so made that the bed-pans are placed on end, so that the water-jet is discharged in the centre and thoroughly flushes them out.

To return to the operating-room, it is provided with Dr. Isaac's electric search-light, which is affixed to the forehead in the same manner as a pair of spectacles and is useful for examining the throat or for speculum work. Messrs. S. Maw, Son, and Thompson provide all the surgical instruments and also an air-tight and dust-proof brass and glass instrument-cabinet. In a case of similar construction the aseptic bandages are kept. The flooring is made of the terrazo mosaic supplied by the Artistic Tile Company. This consists of fragments of marble set in cement. Being liquid when applied it can with great facility be rounded off at the corners so as to prevent the forming of angles where the wall joins the floor. When dry it is hard and impermeable. The same firm exhibits a table such as is used at the Pasteur Institute. It is made of volcanic lava, and is so hard that it can only be cut with a diamond saw. The strongest acids produce no effect upon it and therefore it is considered best adapted as being absolutely non-absorbent. In the operating-room there are aseptic irrigators by which water can be brought to the operating table. It comes direct from the main to a nickle-plated cylinder on a wrought metal stand, containing a sufficient number of Pasteur-Chamberland filtering bougies to ensure a constant current of water. To this cylinder a long india-rubber tube is fixed and the water can thus be brought wherever needed. Throughout the building the Pasteur-Chamberland filter is employed.

Another room is devoted entirely to Roentgen ray apparatus. Dr. Mackenzie Davidson, the medical officer in charge of the x-ray room at Charing-cross Hospital, shows a new zoditory mercury break which can be made to work satisfactorily with any voltage. Here there are many photographs taken from different points of view and combined with the aid of a stereoscope so as to prevent distortion. Then there are various methods of generating the currents required for x-ray work and there is also a portable apparatus for field ambulances.

Finally, Messrs. Thomas Bradford and Co. have fitted up a small, compact laundry which is not worked by steam power. A spraying grid used in conjunction with the soaking tank is new. It is worked with the aid of a hose and reduces the necessity of handling the dirty linen to a minimum. Two small fires suffice to do all the washing, drying, and ironing.

Altogether this exhibition is very compact and contains many things of considerable technical interest in a very small space; moreover, the general public cannot fail to be impressed and interested when they see the scientific care that is bestowed on hospital patients. It is to be hoped that this exhibition will awaken sympathy and increase the subscriptions needed for the continuation of the good work done at Charing-cross and other hospitals.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Changes in Plague Policy.—The Progress of the Epidemic.—The Request for a Plague Expert.—The Serum Treatment of Plague.

AN extraordinary change of policy has been gradually adopted by the plague authorities. Whereas formerly detention of travellers with quarantine and thorough disinfection, isolation of the sick in hospital and segregation in camp of those who had been in contact with them, eviction from dwellings with formation of health camps, and disinfection here, there, and everywhere were actively practised one finds that one by one these measures have been gradually relinquished. During the past week it has been notified that disinfection of native passengers to Naini Tal will be restricted to the soiled linen and dirty blankets of third-class passengers who have travelled from a plague-infected district.

The epidemic wave is gradually falling. The deaths from plague throughout India last week fell to 2498 compared with the 3365 deaths for the week previous. It is improving in Bombay city and also in Karachi, and it is markedly less in Calcutta and the Bengal Presidency. An improvement is also reported from Aden. Bombay city has still a mortality at the rate of over 130 per 1000 per annum, and while having 1400 deaths above the average returns but 448 deaths from plague. While plague is thus improving the numbers on famine relief unfortunately continue to increase. The grand total is now over 5 500,000. The Central Provinces and the Bombay Native States show the largest increases this week.

I understand that considerably more than a month ago the New South Wales Government asked the Government of India for the services of a plague expert, but so much time having elapsed since the request they now intimate that they do not require the services of a plague expert from India.

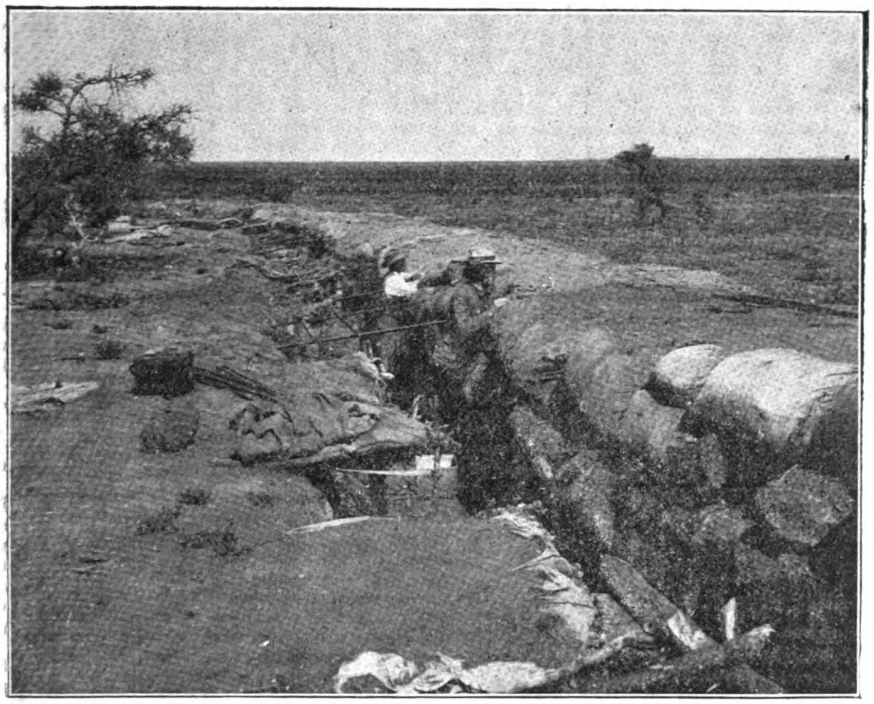
An advocate for the serum treatment of plague after the method of Professor Lustig has appeared in the person of Dr. A. Meyr of the Bombay Municipal Laboratory. In a paper read before the Medical and Physical Society he reviewed the results obtained when the patients were selected for treatment and since then when they have been taken alternately as they were admitted. His figures must be doubted on two grounds—viz., that patients of the later days of disease and moribund and mild cases were excluded. Since May, 1899, some 361 patients were treated, with a recovery rate of 33·8 per cent. The report says that an equal number without the serum treatment only gave a recovery rate of 21·2 per cent. There must here be an obvious fallacy, because without the exclusion of any cases this has been hitherto the average recovery rate of all admissions. 33 per cent., or thereabouts, die within 24 hours. It is clear, therefore, that the exclusion of moribund cases and cases in the later days of disease must considerably improve the recovery rate of the remainder. In fact, exclusion of such cases at once raises the recovery rate 12 or 15 per cent., if not more. If Dr. Meyr could show a real improvement of 12 per cent. it would certainly indicate some promise of future success, but to hold up an improvement of only 12 per cent. after deduction of serious cases over the rate which ruled at the hospitals for all admissions is not very satisfactory. The original Chinese serum was obtained by injecting the horse with living and virulent cultures. This method was thought to be dangerous and was abandoned. Latterly a modified practice has been adopted in Paris. This consists of injecting first of all dead cultures and afterwards living and virulent ones. Serum after this method was used in Oporto and was said to have proved very successful, but here again the same errors were repeated in that similar cases were not taken for comparison. Under these circumstances it is impossible to place faith in the returns notwithstanding that the mortality under the serum treatment is reported to have been five times less than that of cases treated without it. It is very evident that the method of Lustig which has been tried in Bombay falls far behind that which has apparently proved so successful at Oporto. If Lustig's serum possesses any value great alteration must be made in its preparation in order to render it more potent.

May 3rd.

THE BOER TRENCHES.

IN the report in THE LANCET of May 26th of the meeting of the Royal Medical and Chirurgical Society on May 22nd we referred to the lantern slides of the Boer trenches exhibited by Mr. Clinton T. Dent, F.R C S. Eng., in illustration of his address. By the courtesy of Mr. Dent, by whom the photographs were taken, and of Messrs. George Bell and Sons, we are enabled to reproduce two of these slides, which, with several others, will appear in a book Messrs. Bell are about to publish, entitled, "My Diocese during the War," by the Right Rev. the Lord Bishop of Natal. Fig. 1 shows a typical Boer trench at Magersfontein, the foremost figure in which, that of the Bishop himself, gives an excellent idea of the almost complete cover afforded by these deep trenches to those engaged in them. The shelter provided was even more complete than appears in the photograph. Skins were spread over the iron supports laid across the trench, and in these skins earth was piled up. In many places sheets of corrugated iron were laid on the iron supports. The trenches were thus to a great extent bullet-proof, if not altogether bomb-proof. The Highland Brigade advanced along the plain on the left. The front wall is covered with mealie sacks filled with earth. In places loop-holes are made between the sacks. Fig. 2 represents another trench, with a roofed-in shelter behind. On the top of the central kopje was an emplacement for a big gun.

FIG. 1.



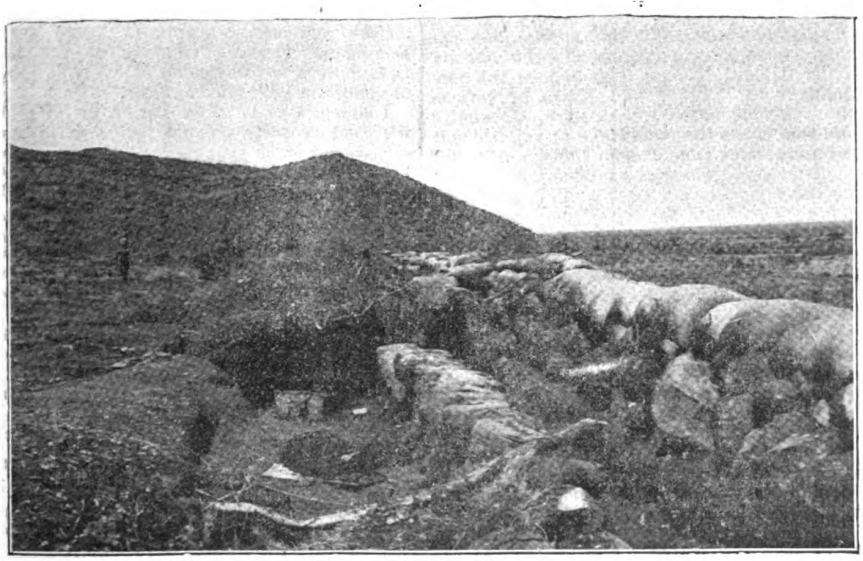


FIG. 2.

ROYAL MEDICAL BENEVOLENT COLLEGE.

THE annual general meeting was held on May 25th Dr. HOLMAN presided and was supported by the following members of council: Mr. John Croft, Mr. C. L Smiles, Rev. E. W. Northey, Mr. H. E. Vardon, Mr. G. C. Croft, Sir Arthur T. Watson, Bart., Q.C., Mr. Stamford Felce, Sir Joseph Fayrer, Bart., Mr. A. E. Cumberbatch, Dr. A. E. Sansom, Dr. J. H. Galton, Mr. Oldaker, Sir R. Douglas Powell, Bart., Dr. M. Baines, and Mr. G. P. Field.

The following pensioners were elected: Annie Blick, John Charles Bonnett, Elizabeth M. Solly, William Dewsnap, Margaret Keith, Ellen Wilson, and Anne Winearl Osborne.

The following foundation scholars were elected: Edward R. L. Warren, Gerald Percy Adams, Charles R. Hamilton, and Cuthbert W. Ellison.

Dr. HOLMAN, in moving the adoption of the annual report, which was in every way a satisfactory one, said: The policy of the council has been to prepare students for entering the profession of medicine and to give to all pupils whatever the course intended for them, a sound, all-round public school education, so that they may be fitted to act not only as medical practitioners or otherwise, but also to hold their own socially in the neighbourhood in which they live. This is in exact accordance with the wishes and aims of the Founder of the College. Epsom College is not a class school, but offers especial advantages to the sons of medical men.

The days of class schools are practically at an end, and it is desired to make our College a public school to all intents and purposes with a medical foundation. Years since it was a common complaint by medical men that they were not given any social status either in private practice or in the public services. It was evident to anyone looking into the question that one cause was the frequent absence of general culture and tone in those who were complaining.

Our object at Epsom is to turn out well-educated gentlemen and students of good tone and high aims, and our experience is that by giving our students the widest education possible we are enabled not only to pass a large proportion through the stiffer medical examinations, but also to ensure their continuing to do well by the avoidance of any sort of cramming. We can often carry them further still and secure university distinctions. I am referring mainly, of course, to those boys intended for the medical profession. Of the general success of other boys I need not touch upon. Our average number of passes in the London Preliminary Scientific and Matriculation Examinations, on which many, though not all, of our valuable hospital scholarships depend, will compare favourably with those of any other school. Of late years we have also gained constantly university open scholarships won straight from Epsom. Between Founder's day, 1896, and Founder's day, 1899, ten open scholarships or exhibitions at the universities have been gained. The two in 1899 were for mathematics. In the *British Medical Journal* of this morning are published the results of inquiries by the General Medical Council into the preliminary examinations in England and Wales by various examining bodies. Matriculation examination, University of London, of all candidates the percentage of rejections is given as 52·2, of candidates from Epsom College it is 35; at the Oxford and Cambridge school examinations for the higher certificate the rejections are given as 43·7, at Epsom it is 20; for the lower certificate the rejections are given as 44·3, at Epsom it is 25. The time has been so limited since I saw these figures that I have not been able to work out our returns in decimals, but the general result is sufficient to show that our teaching is well up to the mark.

Some little time since my attention was drawn to the fact that we could not fill up annually the nine free scholarships most generously given us by the metropolitan hospitals. In all cases it was formerly a *sine quâ non* that the student should have passed both parts of the Preliminary Scientific Examination of the University of London and in three hospitals the first division was required. From our school of under 250 boys, not all of whom enter the medical profession, we could not find nine students out of some 50 leaving each year able to gain these valuable and much-coveted honours on such conditions and it is clearly too much to expect. The senior form has sometimes had less than nine boys in it. This preliminary examination is composed of three subjects, two of which must be taken together and one standing by itself. Candidates from all parts and from many schools and hospitals will vary in age from 17 to 25 years and upwards. On inquiry I found that by far the larger portion of these candidates had to take this examination in two parts and the proportion passing in all three subjects at once was very small indeed and is growing smaller each year. It is no part of my duty to ask why this should be the case, whether it be the result of stiffer examinations or the poorer mental calibre of the candidates. This is another question. Such a discovery gave an ample answer to our position with the hospitals; and when the whole question was laid before the deans of the various schools they at once allowed their scholarships to be awarded to students who had passed a portion of this examination on the obvious condition that the remaining subject or subjects should be passed so soon as possible. That the deans thought our application a reasonable one was clearly shown by their ready acquiescence with our request.

That every year the candidates going up for certain examinations vary much in quality is the experience of all teachers, and that all candidates with the very best intentions on their own parts and every assistance from their masters can be made to pass such examinations is again an assertion opposed to the experience of all schools. The estimation in which a wrangler's degree is held by university men varies greatly, depending upon the class of men who are competing in any particular year. That our boys, as a rule, do succeed in these higher examinations is incontrovertible. In 1899 nine lads went up for the Preliminary Scientific Examination, six of whom passed in *all* subjects and one of these in Division 1, whilst two others passed in one part of the examination and one only failed. Two forms, 25 in number, were sent in bodily for the Matriculation and 16 passed. After much thought and acting on the advice of our head master and other educational experts well qualified to advise, the whole form is usually sent in. A large percentage are expected to pass. The remainder get over the stage fright of their first interview with the examination papers, and also learn what subjects they are weak in and to which they must give more attention. It is helpful both to teacher and taught and a sure test of general efficiency.

I wish it to be thoroughly understood that every boy intended for medicine is given the best possible attention and every chance of success by careful preparation and even (when necessary) by extra tuition; and I may also assert that boys leaving us are so prepared as to be able to take up practically the position of second-year students to whatever medical school they go. I am also able to say that in only one instance of the scholars going to the London hospitals has any complaint on the score of industry or conduct been made during the past ten years, and then a little judicious advice and remonstrance restrained the student who hardly knew how to govern himself when first exposed to the freedom of London after the discipline of school life. Many of our boys obtain minor hospital appointments and some eventually get posts on the staff of the hospitals. There are now eight old Epsomians who are teachers at the London hospitals. Epsom boys are welcomed at every hospital and rarely fail to qualify in their allotted time.

I should like it to be known as widely as possible that with our recently erected junior school buildings we can admit boys much younger than in past years. Boys entering College early are placed in a much better position to command success than those coming later when too often the preliminary education has been of too cramped a character.

The report having been unanimously adopted, a resolution of regret at the Duke of Abercorn's resignation of the office of President was moved by Mr. S. FELCE and seconded by Dr. GALTON. This having been passed, a resolution concerning the appointment of the Earl of Rosebery as President was moved by Sir JOSEPH FAYRER and seconded by the Rev. E. W. NORTHEY. This resolution was also passed and the proceedings terminated with a vote of thanks to the Chairman, moved by Sir JOSEPH FAYRER and seconded by Mr. SMILES.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6230 births and 4098 deaths were registered during the week ending May 26th. The annual rate of mortality in these towns, which had

been 17·8 and 18·2 per 1000 in the two preceding weeks, further rose to 18·4 last week. In London the death-rate was 16·4 per 1000, while it averaged 19·7 in the 32 provincial towns. The lowest death-rates in these towns were 12·3 in Croydon, 12·6 in Cardiff, 13·4 in West Ham and in Birkenhead, and 15·8 in Swansea; the highest rates were 23·5 in Oldham, 23·3 in Salford, 25·5 in Manchester, and 27·4 in Liverpool. The 4098 deaths in these towns included 443 which were referred to the principal zymotic diseases, against 441 and 431 in the two preceding weeks; of these 127 resulted from measles, 126 from whooping-cough, 81 from diphtheria, 39 from diarrhœa, 34 from scarlet fever, 34 from "fever" (principally enteric), and two from small-pox. The lowest death-rates from these diseases last week occurred in Croydon, Birkenhead, Nottingham, and Newcastle; and the highest rates in Derby, Salford, Oldham, Blackburn, and Sheffield. The greatest proportional mortality from measles occurred in Plymouth, Cardiff, Derby, Huddersfield, and Leeds; from scarlet fever in Blackburn; and from whooping-cough in Liverpool, Manchester, Salford, and Oldham. The mortality from "fever" showed no marked excess in any of the large towns. The 81 deaths from diphtheria included 29 in London, nine in Leicester, nine in Sheffield, five in Brighton, and four in Leeds. Two fatal cases of small-pox were registered last week in Liverpool, but not one in any other of the 33 large towns. There were five small-pox patients under treatment in the Metropolitan Asylums Hospitals on Saturday last, May 26th, against five and three in the two preceding weeks; three new cases were admitted during the week, against none in either of the two preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1784, against numbers increasing from 1647 to 1733 on the four preceding Saturdays; 216 new cases were admitted during the week, against 176, 203, and 221 in the three preceding weeks. Influenza was certified as the primary cause of 19 deaths in London. The deaths referred to diseases of the respiratory organs in London, which had been 417, 300, and 270 in the three preceding weeks, further declined last week to 269, and were 27 below the corrected average. The causes of 53, or 1·3 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Bradford, Leeds, Newcastle, and in 12 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Preston, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·7 and 19·5 per 1000 in the two preceding weeks, further rose to 19·6 during the week ending May 26th, and exceeded by 1·2 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 10·6 in Leith and 14·9 in Dundee to 20·5 in Edinburgh and 21·4 in Glasgow. The 606 deaths in these towns included 36 which were referred to whooping-cough, 19 to diarrhœa, 10 to measles, five to diphtheria, three to scarlet fever, two to "fever," and one to small-pox. In all 76 deaths resulted from these principal zymotic diseases, against 63 and 85 in the two preceding weeks. These 76 deaths were equal to an annual rate of 2·5 per 1000, which was 0·5 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 22 and 30 in the two preceding weeks, further rose last week to 36, of which 28 occurred in Glasgow and six in Aberdeen. The deaths from diarrhœa, which had been nine and 15 in the two preceding weeks, further rose to 19 last week, and included nine in Glasgow, three in Edinburgh, three in Dundee, and three in Aberdeen. The fatal cases of measles, which had been 15, 16, and 19 in the three preceding weeks, declined again last week to 10, of which six were registered in Glasgow, two in Edinburgh, and two in Leith. The deaths from diphtheria, which had risen from three to seven in the five preceding weeks, declined again to five last week and included two in Glasgow. The fatal cases of scarlet fever, which had been seven in each of the two preceding weeks, declined last week to three, of which two occurred in Glasgow, where the death from small-pox was also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had declined from 145 to 84 in the five preceding weeks, rose again last week to 94, and exceeded by 14 the number in the corresponding period of last year. The causes of 28, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29·7, 26·3, and 23·0 per 1000 in the three preceding weeks, rose again to 25·2 during the week ending May 26th. During the past four weeks the death-rate in the city has averaged 26·1 per 1000, the rates during the same period being 17 0 in London and 19·5 in Edinburgh. The 169 deaths registered in Dublin during the week under notice exceeded by 15 the number in the preceding week, and included five which were referred to the principal zymotic diseases, against five and nine in the two preceding weeks; of these, three resulted from whooping-cough, two from "fever," and not one either from small-pox, measles, scarlet fever, diphtheria, or diarrhœa. These five deaths were equal to an annual rate of 0·7 per 1000, the zymotic death-rate during the same period being 1·8 in London and 1·2 in Edinburgh. The fatal cases of whooping-cough, which had been four, one, and one in the three preceding weeks, rose again last week to three. The deaths from "fever," which had been six, one, and three in the three preceding weeks, declined again to two last week. The 169 deaths in Dublin last week included 31 of infants under one year of age and 39 of persons aged upwards of 60 years; the deaths of infants exceeded the number recorded in the preceding week, while those of elderly persons showed a decline. Four inquest cases and one death from violence were registered; and 61, or more than a third, of the deaths occurred in public institutions. The causes of 6, or nearly 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeon W. H. Norman to the *Cormorant* for Gibraltar Hospital. Surgeon N. L. Richards to the *Cormorant* for Gibraltar Hospital, Dockyard, and Naval Extension Works.

ROYAL ARMY MEDICAL CORPS.

Surgeon-Lieutenant-Colonel Henry Wright, 1st Volunteer Battalion the Lincolnshire Regiment, is granted the temporary rank of Major whilst serving in South Africa. Lieutenant-Colonel McAdam, r.p., is ordered to Dublin for duty and Captain C. K. Morgan is to proceed from Satara to Poona for duty at the Station Hospital. Lieutenant-Colonel W. F. Ruttledge, r.p., is appointed Sanitary Officer at Aldershot. Surgeon-Major A. G. Grant, I.M.S., r.p., assumes temporary medical charge of troops, Station Hospital, &c., Aberdeen.

VOLUNTEER CORPS.

Rifle: The under-mentioned officers are borne as supernumerary whilst serving with the Royal Army Medical Corps in South Africa:—4th Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Captain E. J. G. Berkley. 3rd (The Blythswood) Volunteer Battalion the Highland Light Infantry: Surgeon-Captain R. Pollok.

Artillery: 2nd Hampshire (Southern Division, Royal Garrison Artillery): Surgeon-Lieutenant Paul McKenna Terry resigns his commission and is appointed Second Lieutenant. 1st Suffolk and Harwich: Surgeon-Lieutenant F. A. Brooks to be Surgeon-Captain. *Electrical Engineers:* John Alfred Masters to be Surgeon-Lieutenant. *Rifle:* 2nd Volunteer Battalion the Prince Albert's (Somersetshire Light Infantry): James Gordon Bain to be Surgeon-Lieutenant. 4th Volunteer Battalion (the Cheshire Regiment): Surgeon-Lieutenant E. C McCarthy to be Surgeon-Captain. 4th Volunteer Battalion the Cameronians (Scottish Rifles): John Souttar McKendrick to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Arthur Thomas Lakin to be Surgeon-Lieutenant.

VOLUNTEER INFANTRY BRIGADE.

Cheshire: Surgeon-Captain H. W. King, 2nd Volunteer Battalion the Cheshire Regiment, to be Brigade-Surgeon-Lieutenant-Colonel on appointment as Senior Medical Officer to the Brigade, vice Brigade-Surgeon-Lieutenant-Colonel A. Hamilton, who resigns the appointment.

Memorandum.—In consequence of the division of the 1st Worcestershire and Warwickshire Volunteer Artillery into two corps the following appointments are made:—1st Worcestershire Volunteer Artillery: Surgeon-Lieutenant A. C. Oldham. 1st Warwickshire Volunteer Artillery: Surgeon-Lieutenant S. P. Johnson.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Lieutenant A. E. Madge resigns his commission.

VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the undermentioned officers:—*North-Eastern District: Rifle:* 2nd Volunteer Battalion, the Prince of Wales's Own (West Yorkshire Regiment) Surgeon-Lieutenant-Colonel Samuel Johnston. 1st Volunteer Battalion, the Leicestershire Regiment: Surgeon-Lieutenant-Colonel Robert Bradshaw Smith. *Scottish District: Rifle:* 4th (Donside Highland) Volunteer Battalion, the Gordon Highlanders: Surgeon-Captain John Osbert Wilson. 7th (Clackmannan and Kinross) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Major Duncan William Currie.

TRANSVAAL WAR NOTES.

Captain Lawson, R.A.M.C., left South Africa invalided in the *Canada* on May 17th.

Dr. William Davies, son of Mr. Ebenezer Davies, medical officer of health of Swansea, who was imprisoned owing to his supposed connexion with the Jameson raid and who was one of the survivors of the siege of Ladysmith, was also one of those to enter Mafeking on May 18th. He was attached to the Imperial Light Horse and took charge of the medical stores accompanying the relief column.

The War Office has decided to build a number of wooden huts near the site of the proposed new infantry barracks at Pembroke Dock for the accommodation of 140 convalescent soldiers returning from South Africa.

Lieutenant-General Sir W. Butler, K.C.B., commanding the Western District, visited the military hospital at Stoke last week to see the convalescent patients who had recently landed from the *Braemar Castle*. At the conclusion of the visit General Butler expressed himself as highly gratified at the general appearance of the hospital and the care and attention bestowed by the staff upon the patients.

By the request of the principal medical officer at Bloemfontein the Langman Hospital of 100 beds has been converted into one of 150, the necessary equipment for which has been provided by Mr. Langman and despatched to South Africa. The medical staff has been increased by the appointment of Mr. W. W. Woolliscroft, late house surgeon to Charing-cross Hospital.

Major S. R. Wills, R.A.M.C., Captain W. D. Erskine, R.A.M.C., and Lieutenant Morris, R.A.M.C., are returning home invalided from South Africa in the *Simla* which left Cape Town on May 21st.

TRANSVAAL WAR CASUALTIES.

The following deaths are reported:—Royal Army Medical Corps: Lieutenant E. L. Munn, enteric fever, Boshof, May 23rd; Major Perry Marsh, enteric fever, Deelfontein, May 22nd.

Mr. F. R. Eames, a dresser attached to the Welsh Hospital, has died from dysentery at Bloemfontein on May 27th.

DEATHS IN THE SERVICES.

Lieutenant-Colonel Aylmer Ellis Hayes, D.S.O., A.M.S., late of the Royal Army Medical Corps. He was appointed surgeon in 1877 and retired with the rank of lieutenant-colonel in 1897. He served with distinction in the operations near Suakin in 1888, including the engagement at Gemarzah, and mentioned in despatches (medal with clasp, third class of the Medjidie, and Khedive's star). He also took part in the operations on the Soudan frontier, 1889 (mentioned in despatches, D.S.O. and clasp).

Brigade-Surgeon-Lieutenant-Colonel William Center, I.M.S., retired, at Ealing, on May 16th. He joined the Indian Medical Department in 1865, and from 1871 served in the Punjab as chemical examiner and professor in the Lahore Medical School. He also at one time was statistical officer in the sanitary department of the Government of India, and subsequently was appointed civil surgeon at Lahore and superintendent of the lunatic asylum.

"Audi alteram partem."

"THE TENURE OF OFFICE OF MEDICAL OFFICERS OF HEALTH."

To the Editors of THE LANCET.

SIRS,—After the annotation under the above heading in THE LANCET of May 12th, p. 1375, some of your readers were scarcely prepared for the leading article on the same subject in THE LANCET of May 19th, p. 1454. Whoever the writer of this ungenerous article may be he is evidently not in sympathy with a very large number of his provincial brethren in the disabilities under which they labour by virtue of the precarious nature of their appointments as medical officers of health. He sees "in the proposal a serious obstacle to the development of whole-time appointments carrying salaries commensurate with the dignity of the office of a specially qualified medical officer of health." Now, the Local Government Board have had a quarter of a century in which to develop whole-time appointments. Are they at all likely during the next 25 years to persuade local authorities to pay salaries commensurate with the dignity of the office? Are not the salaries attaching to whole-time appointments rather rapidly falling, too? In the meantime who are to do the sanitary work in the provinces? Who are doing the work now, and who have done the work in the past? It has been done, it is being done in the present, and it will be done in the future, to the great benefit of the community, by half-time men. These half-time men are not a class of mere officials any more than are Poor-law medical officers, but, for the most part, they are earnest, hardworking, conscientious practitioners of medicine, men of ability, often of social standing—some are magistrates—who are able to exert their influence as citizens and among their patients in favour of sanitary reform. Why should not these men receive the same protection as Poor-law medical officers have? Why should not they be appointed during good behaviour as are the clerks of their authorities who are also engaged in private practice? Is the profession of medicine less honourable than that of law? In what possible manner can such protection prove a serious obstacle to the development of whole-time appointments? Will these men do their work less efficiently because they know they will not be dismissed at the end of the term of their appointment because they have done their duty? Does experience teach that medical officers of health who receive "the paltry salary of some £10 to £50 yearly" are insecure in their office? On the contrary, they already possess security of tenure if they are sufficiently subservient, and if they are not efficient are they likely to become less efficient because they cannot be dismissed without the consent of the Local Government Board, who possibly have not sanctioned their appointments because they have not been asked to contribute to their salaries? But is it a disadvantage to the community that a medical officer of health receiving a salary, say, of £50 yearly is encouraged to do his duty by the knowledge that he cannot be arbitrarily dismissed from his post?

The medical officer of health who requires security of tenure of office is the man who is appointed with the consent of the Local Government Board, who pay a moiety of his salary, and who can be dismissed without their consent—a man whose tenure of office becomes insecure only when he carries out his duties earnestly in the manner which the law prescribes and who advises his authority that it is their duty to spend money in providing water-supplies and sewerage in obedience to the law which they are appointed to administer. And until the Local Government Board take upon themselves the task of coercing sanitary authorities to do their duty they must consent to the enabling the present-day medical officer of health to do his duty without fear or favour if the sanitary interests of the provincial community are to be adequately safeguarded. And the present-day

medical officer of health is a half-time man to the extent of 90 per cent. of the whole number.

In conclusion, permit me to say that many old subscribers to THE LANCET must have read with pain and regret a *doctrinaire* article in which the interests of a large body of honourable members of the medical profession who are doing a great and beneficent public work and who are daily suffering disability and loss of dignity such as no other body of men in the profession suffer, are ignored. The conditions under which they carry on this work is a public scandal which has existed far too long, and, with all courtesy and deference to you, Sirs, I am very much mistaken if the indications are not that the great bulk of the medical profession have definitely made up their minds that it shall cease. I am, Sirs, your obedient servant,

Carisbrooke, Isle of Wight, May 22nd, 1900. J. GROVES, M.D.

THE INFLUENCE OF DUST AND FLIES IN THE CONTAMINATION OF FOOD AND THE DISSEMINATION OF DISEASE.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the Milroy lectures on Summer Diarrhœa by Dr. Waldo and consider that his evidence is as complete as the statistician or medical officer of health can make it, but there is one point concerning the means by which food becomes contaminated to which he barely refers, and to which I, as a practitioner, am inclined to give a very high degree of importance. The point to which I refer is the agency of flies in the direct conveyance of bacteria from filth to food.

In making this remark I wish it to be understood that I do not desire to question in the least degree the immense importance of bacteria-laden dust, especially that derived from horse-dung and other forms of excreta with which the atmosphere of towns is at all times polluted, but I would like to point out that such dust is present at all times of the year when the streets and roads are dry enough to allow it to exist in the form of dust. Contamination of food by means of dust is, therefore, possible at all seasons. Of course, during hot weather the bacteria grow much more rapidly in food, milk, &c., than in colder weather, and are, therefore, more likely to be present in large numbers at the time when the food is ingested. The relative resistance of the gastro-intestinal canal to the action of such organisms or their products, and the question as to whether and to what extent climatic conditions affect such resistance we must leave out of account, as we are arguing now on matters outside the human body. The excellent Table IX.[1] would be still more instructive if it contained the following details, which, however, could only be learned by notification followed by domiciliary visits, or special report on each case drawn up by the practitioner in attendance upon it, on a form supplied for the purpose: (1) number of cases in which food was habitually kept in the living room; (2) number of cases in which the said room was also used for sleeping; (3) number of cases occurring in rooms the windows of which were habitually kept closed; (4) number of cases in which flies were noted to be numerous in the room or rooms at the time of the occurrence of the case; (5) number of cases occurring (*a*) in basement, (*b*) on ground floor, (*c*) first floor, (*d*) second floor, &c., respectively, and whether front or back rooms and how used.

As a general practitioner of over 11 years' standing I have seen a good many cases of summer diarrhœa and have no doubt of its being due to bacterial contamination from alvine evacuations, whether equine, human, or other. I am inclined to think that human excreta have more to do with it than is recognised, the only question is the method of transference. My own experience, which has, of course, formed my own opinion, although it is not very extensive and has not been systematically recorded, is as follows: that the cases occur for the most part amongst the poor and in the following circumstances—(1) in small, ill-ventilated rooms, especially at the back of the house and in the basement; (2) in rooms the windows of which are habitually kept closed and to which the air and dust of the streets have less access than to most others; (3) in rooms used as kitchen, living-room, and often as sleeping-room, the atmosphere of such a room being usually close and often fœtid, the temperature very high, and frequently almost uniform day and night, forming, in fact, an incubator at very nearly the optimum temperature for the cultivation of pathogenic bacteria. Such rooms are, in my experience, always swarming with flies in summer, and I have even occasionally seen them containing fairly large numbers of active flies in winter, owing to the high and uniform temperature at which they are kept. According to Dr. Waldo's showing the incidence of diarrhœa is not greatest in the large streets and thoroughfares which are most dung-laden, but in by-streets and courts.

Now if the disease were due mainly to direct contamination by dust one would expect to find it most in the larger streets where such dust as there is consists chiefly of horse-dung and is kept constantly stirred up. The windows of the houses in such streets are, moreover frequently wide open during hot weather. The dust has, therefore, free access to basements, kitchens, larders, &c. The bactericidal action of air, light, sunshine, &c., on town dust must, as Dr. Waldo says, be considerable, but cannot be completely antiseptic. I think that bacteria are more likely to be conveyed in an active and virulent state by flies which settle at one moment on fresh dung and at the next on milk, meat, butter, sugar, jam, or fruit than by dust which must, if emanating from dung, have been some hours exposed to wind, &c., to have become desiccated and pulverised and to have reached its destination on the food, to say nothing of the strong sunshine to which it is likely to have been subjected at the time of year we are considering in the process of desiccation.

These remarks are based solely on observation and that of no vast number of cases, as I have not practised extensively among the poor upon whom the greatest incidence of infantile diarrhœa falls. Nevertheless, wherever I have seen the summer diarrhœa of infants and of all the varying conditions among which it makes its appearance the one condition which has impressed me as being the most constant and invariable has been the presence and persistent meddlesomeness of the common fly. Granting that the dung of our streets supplies the materies morbi, may not the fly play as important a part as the wind-current in depositing it in an active state on our food? This is, of course, capable of investigation by exposing for a given length of time in a room in which a case of summer diarrhœa has occurred cultivation plates—(*a*) protected from flies but not from dust; (*b*) exposed to flies, incubating both and examining the resulting colonies.

I am, Sirs, yours faithfully,

WM. SALISBURY-SHARPE, M.R.C.S. Eng., L.R.C.P. Lond.

Cleveland-terrace, Hyde Park, W., May 26th, 1900.

[1] THE LANCET, May 19th, 1900, p. 1427.

"THE CONFERENCE ON MEDICAL ORGANISATION AT MANCHESTER."

To the Editors of THE LANCET.

SIRS,—The honorary secretary of the above Conference, Dr. Samuel Crawshaw, accuses me of "destructive criticism" in regard to this meeting. This is, indeed, a surprise and a revelation. For more than five years I have travelled on your behalf and in all directions to investigate the economic grievances of the medical profession and the result has been to point out the absolute necessity of organising medical unions or guilds. Surely all sincere workers in this cause must feel that friendly criticism is far more useful than mere complimentary notices. It is further insinuated that while I pursued the easy course of finding fault I failed in the more difficult task of indicating a remedy. Yet I suggested the fixing of a definite system of representation based on the signing of a pledge and the payment of a subscription, the discussions of the course of action to be followed rather than of grievances, and, above all, the methods and means for bringing men into union. Had this been done more fully then, indeed, the conference would have been something "very different" from "anything previously attempted." I fancied, and still believe, that this is what Dr. Crawshaw and all genuine reformers desire; and I beg him and them to rest assured that far from entertaining any hostile motive my criticisms are solely inspired by the desire of helping forward the cause.

There was, however, one objection which I raised against the Conference; but this I mentioned some considerable time before it was held and not afterwards. Seeing that as yet there are not many genuine medical unions in Great Britain, that their funds are limited, and that not many of the

members can afford to leave their practices for any length of time, I thought that the holding of two congresses within a few months of each other might tend to weaken both these assemblies. Nevertheless, and though this still seems to me a serious consideration, I did not press the matter further, but accepted the explanation given. I was told that it would be very much better for the International Congress of Medical Ethics or Deontology that a Conference should first be held at Manchester, that the delegates whom the Manchester Conference would not fail to elect would be able to attend the Paris Congress in a more representative capacity; for, instead of speaking in the name of their individual societies they would speak on behalf of all those who had met at Manchester. This seemed to me a good and weighty reason and I can assure the delegates of the Manchester Conference that they will be very heartily welcomed by the delegates of medical unions of France and other nationalities who will meet in Paris on July 23rd next. Unfortunately, I am not yet acquainted with the names of these delegates, and I would urge that they should communicate at once with the secretary of the British Section of the International Congress on Medical Ethics.

I am, Sirs, yours faithfully,

May 29th, 1900. YOUR SPECIAL COMMISSIONER.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—The medical profession will thank Captain Clayton Lane, I.M.S., for his outspoken letter. I have now before me the twenty-eighth newspaper report of inquests in England upon persons killed by anæsthetics since Jan. 1st, 1900. The following is the last (*Bristol Times and Mirror*, May 24th):—

HIGHBRIDGE.

DEATH UNDER CHLOROFORM.—A young married woman named Mulford, the wife of a local tradesman, went under chloroform yesterday in order to have some teeth extracted and succumbed to the effects of the drug. The sad occurrence has created a painful sensation in the town.

Not infrequently such reports as this are all that emerges when someone has been killed by an anæsthetic. This is not for the public good. It is not helpful to science. It does not prevent future deaths. Yet some 80 per cent. of these persons are killed before the operation commences—one of this month's cases in one and a half minutes.

If a captain lose his ship, or an officer lose a piece of artillery, he is court-martialled as a matter of course. The burden of justification is cast entirely upon the officer in charge of national property, even in cases where such officer may have nobly done his duty and be obviously entitled to general sympathy. I submit, Sirs, as an ethical principle, that the like burden of justification lies still more cogently upon one who has killed his patient by an anæsthetic. I submit also that no one is justified in giving an anæsthetic in so slovenly a fashion that he cannot afterwards write out an intelligent report of the case. The public and the profession are entitled to a clear and explicit statement of the following facts:—1. The anæsthetic adopted; the amount used; the inhaler employed; the method of administration; and the time-history of the administration, showing the time from the commencement of the administration to the supervention of danger or death. 2. A report on the patient, the results of any examination that may have been made, and whether albuminuria or glycosuria existed. The disease or injury for which the anæsthetic was administered and the operation intended. How far the operation had proceeded at the moment when danger or death supervened. 3. The measures used for resuscitation, how soon instituted, their results. 4. The facts disclosed by a necropsy, if made. 5. The cause to which death was assigned. I am, Sirs, yours faithfully,

Manchester square, W., May 26th, 1900. JAMES EDMUNDS.

THE RÔLE OF EDUCATION IN THE PREVENTION OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—Education is the motto of the associations formed in this country to prevent the spread of tuberculosis. The Devon and Cornwall Association's committee forwarded in May, 1899, and in May, 1900, letters to county councils and boards of education advocating instruction in "health laws or maxims" to scholars in elementary schools. It believes good may ensue by an appeal to the open mind of youth rather than the prejudices of age. In "Moral Instruction to Children" Mr. Adler recommends lessons on duty to one's self, to womankind, and to society, which include personal and public hygiene. It is more than probable that a higher standard of morality would result from improved health. Instruction seems necessary to counterbalance the effects of modern artificial conditions of life seen in tuberculosis.

The National Association for the Prevention of Consumption is shortly considering with branch delegates and others how pressure may be brought to bear on the education authorities to include such instruction in the New Education Code. Locally it is believed it may be taught under "composition," "writing" (copybook headings), or "domestic science." Further, it is possible that education authorities may be actually shown, perhaps, some practical illustrations of defective hygienic arrangements with results.

I am, Sirs, yours faithfully,

F. BUSHNELL,
Honorary Secretary of the Devon and Cornwall Branch.

Plymouth.

TREATMENT OF CHRONIC ECZEMA.

To the Editors of THE LANCET.

SIRS,—I beg to forward you particulars of a case of chronic eczema which was cured by an abscess. The patient was a man, aged 31 years, who for eight years had a patch of chronic eczema as big as a crown-piece situated in the popliteal region over the biceps femoris tendon. He had tried various treatments from time to time, including arsenic, dieting, and total abstinence from alcoholic stimulant. He had also tried "complete" rest and change of air, but treatment seemed to be of no avail. The patch slowly increased in size and the skin became cracked and fissured.

One day he scratched it and it became infected with pyogenic organisms. An acute abscess formed accompanied with a good deal of cellulitis and lymphangitis. The abscess was opened and the patient was well in a week. This happened a month ago and the patch of eczema has entirely disappeared. I attribute the cure to the increased vascularity of the surrounding area produced by the inflammation. (This, of course, will not apply to the cicatrix.) I venture to suggest that counter-irritation of the skin by increasing the vascular supply might prove a beneficial method of treatment. I should be glad if some of your readers having experience of similar conditions would kindly give me the benefit of their opinion.

I am, Sirs, yours faithfully,

PERCY AUGUSTUS LONGHURST, M.R.C.S. Eng., L.R.C.P. Lond.

Old Burlington-street, May 14th, 1900.

*** A probable explanation of the above interesting clinical observation is that the chronic eczema was microbic in origin and that the microbe was destroyed by the toxins of the pyogenic cocci. It is being gradually recognised that many conditions grouped under the wide term eczema are due to the presence of micro-organisms.—ED. L.

SAVE ME FROM MY FRIENDS.

To the Editors of THE LANCET.

SIRS,—My attention has been called to various paragraphs which have appeared in the lay press with reference to the case of a private patient of mine. Will you allow me to say that they have been inserted without my knowledge or consent and that they have caused me much annoyance.

I am, Sirs, yours faithfully,

G. ANDERSON CRITCHETT.

Harley-street, Cavendish-square, W., May 30th, 1900.

MYLES *v.* FITZGIBBON.

To the Editors of THE LANCET.

SIRS,—In consequence of Mr. Myles's refusal to allow me to embody in my letter of apology, dated the 24th inst. and published in the Dublin press of this date, my explanation as to how I fell into the serious mistake as to a matter of

fact appearing in the circulars addressed by me to the Fellows of the Royal College of Surgeons in Ireland, it becomes necessary for me now to publish my explanation through the medium of the press. The mistake referred to arose from the publication of Mr. Myles's acceptance of the offer of the freedom of the city of Limerick having appeared in the *Evening Telegraph* immediately in succession to the report of the meeting of the United Irish League and being assumed by me to have been part of the proceedings at that meeting. I was not aware of my mistake until I read in the Dublin evening papers of May 23rd the report of the motion for an injunction in which paragraphs from an affidavit made by Mr. Myles were quoted. As soon as I became aware of the error into which I had fallen I tendered through my solicitors to the legal adviser of Mr. Myles a complete apology.

I am, Sirs, yours faithfully,

HENRY FITZGIBBON, M.D.

49, Merrion-square, Dublin, May 25th, 1900.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Small-pox at Stalybridge.

THE unfortunate importation of small-pox into Stalybridge was under discussion at the Cheshire County Council meeting held on May 15th. The patient was a man who had been putting up machinery in Russia and who left Moscow on April 17th "suffering from a bad form of confluent small-pox." On this side of the water he travelled by Queenborough, London, and Manchester, reaching Stalybridge on April 20th. He was seen by a medical man and removed to the Hyde Small-pox Hospital, where he died next morning. Everything possible was done locally to prevent the disease from spreading, but up to May 15th there had been two more cases at Stalybridge, and several cases have occurred since. Seven cases have been removed for hospital treatment. Four cases were sent away on May 24th, three of them from one house. Two were removed during the week from Ashton-under-Lyne to the Oldham Hospital. Mr. F. J. Roberts-Dudley of Stalybridge has issued an infectious disease proclamation, and no doubt all efforts will be made to limit the epidemic. It appears also that three men who travelled with the deceased from London contracted small-pox, and as they lived respectively at Bolton, Oldham, and Carlisle, the area of possible infection is tolerably wide. In a letter to the medical officer of the county from the medical officer of health at Stalybridge the latter gentleman says that he could not make out why the man was not stopped at Queenborough or in London. No doubt many other people will feel the same difficulty and probably a good deal of indignation at the evident carelessness that sometimes obtains at our ports with respect to the entry of infectious diseases. It was moved and carried in the county council—

That a communication from the Council be sent to the Local Government Board with a strong expression of opinion that proper precautions were not taken for the protection of the population.

In Stalybridge just now "revaccination is common."

Sale of Drink to Children.

A meeting was held in the Manchester Town-hall on May 22nd in support of Mr. Souttar's Bill for preventing the sale of drink to children. The Rev. Canon Kelly submitted for adoption a draft form of memorial in behalf of the Bill to the local Members of Parliament and a petition to Parliament to the effect that the Bill might become law during the present session without amendment, which was carried. It seemed to him that "it was more dangerous for one who was between the ages of 13 and 16 to enter a public-house than it was for a child of tender years." The licensed victuallers of course oppose this Bill for various reasons, but one point they wish to make against it is that it is more dangerous to the morals for a young person 18 years of age to hear the conversation of the public-house than for one of 16 years, so that, presumably, they would, out of regard for the morals of the community, allow visits to the public-house to buy drink by the youngest children who could carry a jug or a bottle, but forbid it at a later age. It has not, however, been stated at what age after early childhood the licensed victuallers consider that the morals of the young will be improved by visits to the village public-house or the ginshop. The Manchester Corporation has passed a strong resolution in favour of the Bill.

Chorlton Board of Guardians.

Mr. Jenner-Fust, Local Government Board Inspector, distributed praise and blame at the meeting of the Chorlton Board of Guardians on May 25th. He began with the former and congratulated the board on the excellent arrangements at the cottage homes at Styal, and paid the superintendent a high compliment on the way in which the children were cared for. He then referred to the workhouse infirmary at Withington and made various criticisms. It appears that there is some want of classification, for he said it was desirable that some alteration should take place in the system which at present grouped in the same rooms children suffering from whooping-cough, ringworm, and women suffering from a variety of complaints. He drew attention to the fact that there were only straw beds in the infirmary. "Although straw was an excellent thing he thought that an improvement would be effected by the introduction of horse-hair beds." He did not like the corduroy suits for the inmates and said that they were not generally worn in workhouses nowadays. So fashions change. As to the imbeciles they did not know yet what was to be done, but having regard to the overcrowding that at present existed in the infirmary and the continuous increase of the population, "they ought not to hesitate in proceeding with schemes for increasing the accommodation." There is already a scheme for enlarging the cottage homes recently built which it was thought at the time were on a sufficiently large scale, but Mr. Jenner-Fust considered that they would be quite justified in building a new nurses' home, a new laundry for the infirmary, and in entirely separating the infirmary from the rest of the workhouse. Mr. Mainwaring, the chairman, said that they would all rejoice in being able to remove the imbeciles from the workhouse and that they were in hopes, although at present the difficulties seemed insurmountable, that the two unions of Manchester and Chorlton would be combined. It is considered by the board that the former does not bear its fair share of taxation for the relief of the poor and that this very great work would be facilitated by the two unions becoming one.

May 29th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Public Health of Dublin.

THE report of the committee appointed at the instance of the Lord Lieutenant to inquire into the public health of Dublin was issued on May 17th and contained little that was novel or unexpected. The tenements house evil occupies the foremost place as the prime cause of the abnormal death-rate of Dublin, and the noxious features of these dwellings are described in vigorous language. It is satisfactory to note that the committee do not see their way to blame the soil on which the city is built for the prevalence of enteric fever. There is every reason to think it a preventable disease, but the committee are of opinion that the causes of its prevalence in Dublin are not yet thoroughly understood. The important statement appears that "the hospital accommodation for infectious cases in Dublin is larger in proportion to the population than is the case in any English city." In reference to the notification of infectious diseases it was the general opinion of all the witnesses who were examined that this measure should be made compulsory in the districts surrounding Dublin. The committee concur in this opinion and they point out that "such notification is already compulsory throughout Great Britain as it ought to be throughout Ireland." Among the recommendations made by the committee the most novel and debateable was to the effect "that the duties of medical officers of health should no longer be discharged by the 16 dispensary medical officers, and that in future these duties should be discharged by an assistant medical officer of health who should receive an adequate salary and who should give his whole time to the duties of his office." The Dublin *Daily Express*, in commenting on the report, states that it proves that the sanitary authorities have failed to discharge some of the most pressing and important of the duties which devolve on those who are supposed to safeguard health in a

community. In connexion with the same subject a recent article from THE LANCET was quoted with an account of a wake held in the neighbourhood of Fitzwilliam-place, a wealthy and fashionable street of Dublin. The editor of the *Daily Express* goes on to say that this, if true, shows a clear case of neglect on the part of the sanitary authorities, for, as THE LANCET points out, there are laws which sanction the application of the necessary sanitary measures.

Royal College of Surgeons in Ireland: Election of President.

The unpleasant contention with reference to the coming election at the Royal College of Surgeons in Ireland raised by a circular letter from Mr. Henry Fitzgibbon to the Fellows of the College on May 21st, in which he offered himself as a candidate for the Presidency in opposition to Mr. Myles, has been brought to a satisfactory conclusion. An injunction to restrain Mr. Fitzgibbon from publishing his circular was at once obtained by Mr. Myles. On May 24th, however, a full and ample apology was written by Mr. Henry Fitzgibbon and forwarded to all the electors. He at the same time formally withdrew his candidature for the Presidency of the College. By a circular letter dated May 25th he concluded the correspondence, and in referring to his retirement from the contest informed the Fellows that he had fallen into a serious error as to a matter of fact, the mistake having arisen from misconstruction of a report which appeared in an evening paper with regard to Mr. Myles. The latter is now unopposed and will be duly elected President of the College on June 4th.

Notification of Infectious Diseases in Dublin.

A printed circular dealing with the notification of infectious diseases in Dublin was issued by the corporation on May 25th and sent to all the medical men in practice in the city. It specifies the diseases which must be notified, including cerebro-spinal meningitis, which has been added to the list—but only for the next four months. As to phthisis, attention is called to the fact that although it is not included in the list it is desirable to disinfect the rooms in which persons affected by this disease have resided; moreover, the circular points out that notification (which will be regarded as confidential) with a view to disinfection will be gladly received and acted upon. The attention of the Public Health Committee having been called to the fact that some medical men refrain systematically from notifying cases of infectious disease, the committee have resolved to prosecute any medical man who neglects to discharge this duty in compliance with the law of the land. The Registrar-General for Ireland has recently added a new tabular feature to his reports relating to the number of cases of infectious disease notified to the Public Health Committee and the corporation and has stated that it is his intention to furnish this information for each week in future.

Death of Dr. Edward Johnston Quinan of Dublin.

Dr. E. J. Quinan, a physician well known and highly esteemed in Dublin for many years, died on May 26th at his residence in Harcourt-street, aged 86 years. He was an M.D. of King's College, Aberdeen, a Fellow of the Royal College of Surgeons in Ireland, and formerly one of the Court of Examiners there. Dr. Quinan filled the office of honorary secretary to the Irish Medical Association for 40 years and received an address and a presentation piece of plate in recognition of his long and distinguished services to the Poor-law medical officers of Ireland.

The Poor-law Medical Officers of Ireland Vacation Leave.

The disappointment caused among the Poor-law medical officers of Ireland by the recent decision of the Queen's Bench Division, which declared that the Local Government Board had no power to insist on the maximum four weeks' vacation, has been turned into joy by the statement of Mr. Gerald Balfour, contained in his speech in the House of Commons on May 24th. The Chief Secretary for Ireland said: "It appeared that one of the general rules which was passed for dispensary districts was that the medical officers should be allowed four weeks' vacation. The County-court Judges ruled that the Board's action was correct and legal, but the Supreme Court, to which the case was carried, declared that the Board under its rule had no power to insist upon this four weeks' maximum in every case. This, however, would be met by the issue of a new rule, and it would be altered in due course."

The Outbreak of Typhoid Fever in Belfast.

From the report of the medical superintendent officer of health I learn that the total death-rate for the week ended May 19th has been 22·2 per 1000 and for the principal zymotic diseases 2·7. There were 58 cases of typhoid fever notified during the past week, which is a further increase in the weekly number of cases notified. It is stated by a correspondent in a Belfast paper that although the Water Commissioners got a Bill passed 12 months ago enabling them to purchase or deal with the farms lying within the catchment areas of their reservoirs at Carrickfergus and Stoneyford, on the ground that the proximity of these inhabited farmsteads to the reservoirs was a source of danger by polluting the water, no steps have been taken to acquire these farms. If the farms are a source of danger they should be dealt with at once; if not, the owners should be put out of suspense as to whether they are to be dispossessed or not.

Queen's College (Belfast) Athletic Sports.

The annual sports in connexion with the Queen's College Athletic Club took place in the grounds of the North of Ireland Cricket Club on May 26th and were largely attended and in every respect were a great success.

The Samaritan Hospital, Belfast.

A fête and fancy fair on behalf of this hospital will be held in the grounds of Norwood Tower, Belfast, in June.

May 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Temperance Manifesto by the Academy of Medicine.

IN my letter which appeared in THE LANCET of May 19th (p. 1472) I mentioned the circular of General Gallifet, the Minister of War, which forbade the sale of alcoholic liquors in canteens and other places of military resort. Immediately upon the issue of this circular the Academy of Medicine sent its congratulations to the Minister. In an address voted upon the motion of M. Bergeron and M. Laborde the Academy recalls the fact that in its capacity of guardian of those principles of hygiene which dominate the public health it cannot remain indifferent to any prohibitive measures which commence to put into practice those indispensable rules which it has never ceased to advise as warring against the progress of alcoholism. Further, the Academy considers that this beginning should be at once followed by a complementary measure—namely, the forbidding of alcohol in other State departments. Finally, the Academy hopes that the Government will be induced to pass laws calculated to prevent the ever-increasing ravages of alcohol in civil life. The Academy has in view the seafaring population, the mercantile marine no less than the navy, and especially the fishing classes amongst whom alcohol has brought about terrible results. So bad are its effects among the peoples of Brittany and Normandy, who were formerly so wonderfully healthy, that it is considered that unless prompt action is taken the race will shortly disappear. Among the Icelandic and Newfoundland fishing fleets alcohol in the form of a particularly vile brandy is the most essential part of the fisherman's food-stuff. Even in the navy there is a daily distribution of *tafia*, the dose of which is doubled in bad weather or in times of extra work. The Academy is to be warmly congratulated upon its action, for the work to be done is still very great.

The Surgical Treatment of Facial Neuralgia.

M. Chipault, who has made a specialty of the surgery of the nervous system, read some most interesting observations before the Academy of Medicine at the meeting held on May 15th. The surgical treatment of rebellious forms of neuralgia has hitherto given very unsatisfactory results. Peripheral resections of the trigeminal nerve are not dangerous, but give relief lasting only a few months. Resection of the Gasserian ganglion gives better results, but is a dangerous operation, for the mortality rate is not less than 25 per cent. On the other hand the pathology of facial neuralgia which so often arises as an accompaniment of a condition of arterial sclerosis would lead one to imagine that it is a condition of vaso-motor origin. Anyway, many of

the symptoms which accompany it are of vaso-motor origin and go to prove that there exists some common cause, not of the neuralgia itself, but of something which sets the neuralgia in action. Given these conditions it is a logical mode of treatment to employ resection of the superior cervical ganglion of the sympathetic, a ganglion which furnishes vaso-motor filaments, not only to the branches of the trigeminal, but also to the Gasserian ganglion and its central roots. M. Jaboulay had a successful case under this treatment. After consultation with M. Abadie, M. Chipault decided to perform the operation upon a man, aged 60 years, who for 38 years had suffered from a very persistent and acute form of neuralgia which increased in severity as time went on. The pain was especially marked in the region supplied by the superior maxillary nerve. After everything had been tried without success, more particularly opium and sulphate of quinine, the patient underwent the above-mentioned operation. Within 48 hours afterwards his pain had gone and he experienced nothing but a slight feeling of heat in the gum. This case bears out the correctness of the theory that facial neuralgia is due to some vaso-motor cause. M. Chipault remarked that this operation is neither dangerous nor disagreeable, a fact which he had demonstrated by having performed it in some 50 cases. Moreover, the scar is in the neck and not in the face and, therefore, hardly visible, and the patient is spared the subsequent annoying anæsthesia, which is so trying a feature of operations upon the trigeminal nerve.

Sanitary Measures against Plague.

Following on the excitement produced in France by the announcement that plague had appeared at Port Said the precautionary measures set on foot by the authorities have been doubled. Dr. Proust, Inspector-General of Public Health, and M. Catelan, director of the Health Department of Marseilles, have inspected the lazaretto at Frioul and have satisfied themselves that the establishment is in good working order. Stringent precautions have been set on foot to prevent the spread of plague from this port. All ships coming from infected ports are rigorously disinfected and the passengers are kept under strict observation. The French Consul at Alexandria has sent to the Government a telegram addressed to the Chamber of Commerce at Marseilles stating that a passenger who was shipped from Arabia as plague-stricken had been found to be simply suffering from intermittent fever and that quarantine restrictions were relaxed in the case. He was sent to Suez and he arrived there in perfect health. Dr. Flaissières, the Mayor of Marseilles, with a view to encouraging the destruction of rats by which plague is spread, has published a notice that a reward of five centimes per rat and two and a half centimes per mouse will be paid for every one of these animals handed over either living or dead.

Professional Secrecy and the Law.

The Criminal Division of the Court of Cassation has just given a decision declaring that a statement made in court which violates professional secrecy is not evidence. The matter arose out of evidence given by a midwife at the hearing of a criminal charge. She had been consulted by a girl whom on examination she had found to be pregnant and who was afterwards prosecuted for concealment of birth. The Public Prosecutor appealed against the judgment of the Correctional Court of Lure, which had acquitted the prisoner, and the Court of Besançon having considered the arguments of the defending counsel decided that the midwife's evidence was inadmissible and confirmed the judgment of the Correctional Court. The Public Prosecutor having appealed against this decision, the Criminal Division of the Court of Cassation on the case coming before it dismissed the appeal of the Public Prosecutor of Besançon and delivered a judgment which lays down that the duty of professional secrecy necessarily implies that those bound by it shall not, even when called upon to give evidence, reveal matters entrusted to them in the practice of their professions. The Court further went on to state that the law cannot insist upon statements made in violation of professional secrecy being included in the evidence against an accused person, and it pointed out that the judgment of the Correctional Court acquitting the accused of the charge of concealment of birth was based on the fact that the testimony of the midwife at the hearing of the case (to the effect that she was consulted by the accused and had come to the conclusion that the accused had been six months pregnant) was evidence of a secret of which the midwife only became aware through the accused person consulting her in her professional capacity.

May 29th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Plague at Port Said.

IT was on the last day of April that two suspicious deaths occurred among some Greeks living in the European quarter of the town and it was soon proved by bacteriological examination that both of these deaths were from plague. Medical officers, trained disinfectors, and all the necessary equipment of a hospital were at once despatched from Cairo and Alexandria to Port Said, the Government issued the necessary regulations for times of epidemics, and war was formally declared against the bacillus. Steps were taken to try to find out whether there had not been earlier undiagnosed cases of the disease, and an analysis of the death certificates signed by European medical men practising in Port Said revealed the fact that during April three deaths had been certified as due to "influenza with phlegmons," and "cerebral influenza." Death had ensued in these three cases after a few days' illness, and from notes furnished by the courtesy of the practitioners it is now certain that all three were typical cases of plague of a virulent kind. The earliest case was that of a Greek who was taken ill on March 28th and died on April 7th with pneumonic symptoms and cervical buboes. Careful examination of all death returns shows that there is not, and has not been, any excessive mortality in the town, and therefore the disease has been discovered before it has had time to assume any dangerous proportions. Mr. Pinching, the Director-General of the Sanitary Department, reports that all his preparations are now completed. A hospital is ready for 50 patients, organised gangs have been formed for disinfecting, for whitewashing, and for the removal of rubbish, and the Government has voted a credit of £10,000 for the necessary expenses. But it will be necessary for all the consuls and the European residents to do their best to aid the sanitary officials in carrying out all necessary orders. The difficulty does not arise so much with the disposal of the sick or of the dead, but with the friends who have been in contact with the sick, and yet these, whatever their nationality, must for the public good be kept under medical supervision for a few days. Another trouble is that the foreign local press amuses itself, as it did last year in Alexandria, by denying the existence of plague and by deriding the efforts of the English sanitarians. It is unfortunate that the representatives of the foreign Powers here are not disposed to silence these writers who do a decided amount of harm among the lower and more ignorant classes where plague most easily finds its victims. One person has also been found dead at Alexandria—an Egyptian rag-picking woman. There is, as yet, no evidence of how the plague reached Port Said, but it is known that a large commerce in second-hand clothing is carried on between the crews of vessels passing through Port Said and the provision boats of the town. Close to the house in which three cases of plague have been found is a large store of this kind of cast-off clothing.

Hotels at Assouan.

Winter visitors at Assouan are now provided with a choice of three hotels, one of which is the old one in the town itself and has 110 bedrooms and is found chiefly useful for tourists who only want to stay for a few days and see the sights. The two new hotels belong to rival companies and therefore compete with each other to the great advantage of tourists wishing to spend a month or two on the spot. They have both been opened this year, they are both carefully chosen as regards site and sanitation, and they are both designed by English architects. The Berkefeld filter is used in all the hotels and the filtering candles are ordered to be boiled every three days. Bath-rooms, electric lighting, and a library are to be found in the two new hotels. One of them, built on the site of the former English military hospital, has Tobin tube ventilators in every bedroom, fire-taps and plugs on every floor, and splendid views from a liberal allowance of balconies, and is far removed from all the bazaars and native parts of Assouan. This building discharges its drainage into cesspools in the

gardens, while the other hotel, overlooking lovely islands of rocks, employs earth-closets and a cemented cesspool for slop-water. An English church for 300 people has just been built and the town is rendered a little more gay by the presence of the 10th Soudanese regiment with its English officers.

Cairo, May 13th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Antitoxin and the Diphtheria Death-rate in New York.

A STRIKING demonstration of the value of the antitoxin treatment of diphtheria has been officially given by the Health Department of this city. During 1899 there were in the entire city of Greater New York 11,550 cases of diphtheria with 1925 deaths, giving a mortality of 16·6 per cent. In the borough of Brooklyn the antitoxin treatment is not as popular as in the other boroughs and results show that in that borough in 2894 cases 744 deaths occurred, giving a death-rate of 25·7 per cent. In the borough of Manhattan, where antitoxin is being much more extensively used, out of 7612 cases only 960 proved fatal, giving a death-rate of 12 6 per cent., just 50 per cent. less than that of Brooklyn.

The Comparative Efficiency in Steam Disinfection of Flowing Steam and of Steam with a Vacuum.

Surgeon Carter, of the Marine Hospital Service, states that observations having shown that steam introduced into cylinders under pressure but without continuous outlet left "dead spaces" of less than 212° F. and penetrated pillows, mattresses, rolls of cotton quilts, &c., very slowly, the attempt was made at Gulf Quarantine to remedy this (slow penetration) by turning on a considerable head of steam and allowing it to escape freely, but little pressure in the chamber being aimed at. At first several (four) outlets were provided which were closed or opened at will so as to direct the steam to or from any part of the (rectangular) chamber. This was found to be unnecessary, as good results (as far as "dead spaces" were concerned) were obtained by letting the four run at such a degree of opening as to register 214° to 216° F. in the chamber—about one and a half to four pounds' pressure. Surgeon Carter further reports that he found that articles which had been penetrated slowly by still steam were penetrated rapidly by flowing steam. Of these test articles wads of cotton quilts were the most difficult to penetrate and feather pillows came next. Mattresses, such as were in use, were penetrated readily, and blankets under any condition of roll or wad very readily. Indeed, in the latter the electrical thermometer would ring (100° C.) almost as quickly as in the open. These observations were made with two electric thermometers, giving the time at which 100° C. was reached. The method by flowing steam is by far the more efficient—that is, it secures penetration more readily as compared with the vacuum method, provided articles be hung up or loosely packed, taking more time, however, for pillows, quilts, &c. Where, however, it is desirable to lay things flat, which is necessary with the clothes of first-class passengers to prevent wrinkles, creases, &c., or where one must put a large amount of clothing in a chamber, the vacuum offers advantages which are very considerable. With a chamber of the same size the same amount of efficient work will be less injurious, as the goods will come out with the same folds as they had in the trunk.

The Number of Ruptured and Crippled Patients in New York.

Dr. Taylor states that the hospital for the ruptured and crippled has treated since its organisation in 1863 more than 100,000 patients in its orthopædic department, and treats between 4000 and 5000 cases annually. The orthopædic hospital and dispensary treats over 1000 new cases annually. These two institutions have treated about 50,000 orthopædic cases in the last 10 years, and have now under treatment about 10,000 cases. There are besides large orthopædic clinics at the polyclinic, post-graduate, St. Luke's, and Roosevelt hospitals and the Vanderbilt and Bellevue clinics, and many cases are treated in the general hospitals and dispensaries. It is safe to say that not far from 15,000 cripples are being treated in the charitable institutions of the borough of Manhattan. One-third or more of them, say 5000, are of school age, and of these about three quarters come from the borough of Manhattan, or 3500. Some of these are not severely crippled and may attend the public schools; on the other hand, many who would be eligible for the cripple schools are not being treated in the clinics.

Deaths, Disabilities, and Liabilities Incidental to Occupation.

The Commissioner of the New York Bureau of Labour reports that there are probably not fewer than 40,000 injuries sustained annually by the people engaged in the manufacturing industries of this State. Many of these injuries are trivial, entailing little loss of time, but there could not have been fewer than 6000 injuries that entailed disablement for a period in excess of three months. The number of employés covered in this investigation was 452,425, scarcely half the number engaged in manufacturing industries in the State. The number of injuries reported exceeds the number regularly reported to the factory inspector, which has never reached 1800 per annum among 700,000 employés of inspected factories. The number of injuries is even now understated as many firms fail to report accidents. The ratio of injured to each 1000 employed was 16·11. The total number of working days lost by 1330 injured persons was 19,587, which is a per capita average of 15 days or slightly more than two weeks. The action of the State for the prevention of accidents is as follows: first, to require employers to erect and maintain safeguards about machinery at the direction of the factory inspector; secondly, to place upon the employer a financial responsibility to his employés, to be enforced through an action for damages by the injured person. The former policy has undoubtedly prevented many accidents and its results appear in the most favourable light in the reduction of the number of accidental injuries sustained by railway employés since the passage of the Federal law requiring the adoption of automatic couplers. The annual reports of the factory inspector of this State furnish ample testimony of the need as well as the benefits of such legislation, as does also the report of the inspector of boilers in the Department of Public Works.

Ingredients of Oleomargarine.

The effort to prevent the sale of oleomargarine for butter by legislation has thus far proved a failure. It is alleged that in the State of Pennsylvania alone 15,000,000 pounds of oleomargarine are annually sold for creamery butter. A Bill is now before Congress designed to supply new safeguards against this fraud upon the public and in order to obtain an authentic statement as to the ingredients of oleomargarine the Secretary of the Treasury was called upon to furnish the information. He reports that for the fiscal year ending June 30th, 1899, the following were the percentages which each ingredient bears to the whole material:—neutral lard, 34·27; oleo oil, 26·82; cottonseed oil, 4·77; sesame, 0·53; colouring matter, 0·16; sugar, 0·12; glycerine, 0·01; stearine, 0·007; glucose, 0·003; milk, 15·55; salt, 7·42; butter oil, 4·76; butter, 1·72; cream, 3·86. It has been believed that cottonseed oil constituted at least one half of the quantity of all the ingredients employed in the making of oleomargarine, but the report shows that only about 4 per cent. is actually used, while upwards of 34 per cent. of neutral lard enters into the composition.

Liability for the Infection of an Assistant.

A surgeon who was treating an infectious sore on a man was assisted by the patient's wife whom he assured that no risk of infection would be incurred. The wife is alleged to have become infected and she brought a suit against the surgeon. The Supreme Court of the State held that when the surgeon advised the wife he assumed the obligation to use due care in so doing; that the case was one of positive action not merely one of failure to act; that the fact that his duty as to her was merely to advise and not to administer treatment was immaterial; that the situation was such that she needed the advice of a physician and that the surgeon knew it; that he knew of her danger and negligently advised her as to it and that she was injured by following his advice; that if the contract to attend the plaintiff's husband were eliminated from the case the liability would be the same; and that the gratuitous character of the services rendered to the plaintiff would not excuse the defendant's failure to exercise such care as the circumstances demanded. It was urged that there would have been no danger but for pricks in the plaintiff's fingers of which the defendant was ignorant, but the court held that there was danger unless the plaintiff's hands were free from the slightest wounds, and it cannot

be said as a matter of law that a perfect physical condition is so common that the defendant could reasonably rely upon it in giving advice.

Boards of Health in Porto Rico.

The Porto Rico Department Commander has issued an order requiring the establishment of a Board of Health in every municipality of the island. Each board is to be constituted as follows: the alcalde, a municipal physician, the President of the School Board, and the President of the Board of Charities, all of whom must be residents of the municipality in which they serve. Each municipality must have at least one municipal physician, but if the population exceeds 10,000 there shall be not less than two physicians, and for every 6000 above this number there shall be an additional physician. These physicians must attend all calls made by the sick poor. On the creation of these Boards of Health the island will be supplied with a very complete sanitary government.

A Dinner to Dr. A. Jacobi.

A notable event in medical circles during the last week in New York was a dinner given to Dr. A. Jacobi on his seventieth birthday. Congratulations were received from the principal capitals of Europe as well as telegrams from prominent physicians in this country. For 40 years Dr. Jacobi has been a very active member of the medical profession of this city and country, and at the same time he has been a public-spirited citizen. While he was President of the Academy of Medicine he secured a large endowment for its library which has made it prospectively the most complete medical library in the world.

May 19th.

Obituary.

GEORGE BIRD, M.R.C.S. ENG., M.D. ST. ANDREWS.

DR. GEORGE BIRD, who died at his residence in Hampstead on May 4th, as we have already announced in our columns, was a very well-known man. He was born in 1817, being the son of James Bird, a man who took a high place among the poets of his own county of Suffolk and who could put forward claims to other than local fame. George Bird was the eldest of 16. When quite a lad he desired to study medicine and never repented his youthful bent, but always declared the medical life to be the best life a man could lead. After a period of apprenticeship to a country practitioner—a Dr. Wilson, who had the honour of being summoned to attend King George IV. as a gout expert—George Bird went to London and studied at University College. In 1841 he took the diploma of M.R.C.S. Eng. and at once set up in private practice. In 1859 he took the degree of M.D. at St. Andrews. In 1861 he removed to Welbeck-street, where he practised for 33 years. As a student he had a struggle with poverty and to make ends meet engaged in journalistic work. His eager literary sympathies, his sensitiveness to style and expression, were inherited endowments. He was consistently Liberal in politics. As a lad he wore yellow at a Suffolk election when there was scarcely another badge of the colour to keep him company. His pen was always employed in advocating advanced reforms. Throughout life he was a strenuous upholder of every cause that seemed to him to make for the good of the people, and even when he found himself in a minority—a position which, like most uncompromising pioneers, he often occupied—his advanced opinions were always treated respectfully by his opponents because he held them in such a genuine and spontaneous way. He never seemed to come into collision with the very opposite views of other people, for he respected all honest convictions; hence, in spite of his pronounced views, he made friends of all shades of opinion, and it was a noticeable fact that a great many of his patients were transmuted into friends. There was a mutual attraction between him and literary and artistic people. He keenly sympathised with the subtleties of the poetic and artistic temperament. He had read and travelled largely, having been to Egypt no less than seven times, so that he had much to say on many subjects. One of the earliest of his distinguished patients was Leigh Hunt. He also attended Charles Dickens, Sir Edward Bulwer Lytton, Frank Stone (the father of the present Royal Academician), Sir Richard Burton and Lady Burton, R. H. Horne, Thomas Woolner, R.A., the sculptor and poet, Mrs. Lynn Linton, the novelist, and a host of poets, writers, actors, and actresses of the present day. He had a faculty of inspiring hope; and patients, especially patients who thought themselves worse than they were, found reprieve in his voice and bright aspect. In 1895 he retired to Hampstead. He never ceased to be young-hearted and continued in sympathetic touch with all the great subjects of human interest until his death at the ripe age of 82 years. He had "the youth of old age" and not its decay. All his faculties were clear until the end.

THOMAS ALFRED PERRY MARSH, L.R.C.P. LOND., M.R.C.S. ENG.,

MAJOR, ROYAL ARMY MEDICAL CORPS.

MUCH sorrow is felt in Bristol and Newport (Mon.) at the death of Major Marsh who died from enteric fever at Deelfontein, South Africa, on May 22nd, in his forty-fifth year. The deceased, who was the youngest son of the late Captain H. G. Marsh, J.P., of Winterbourne, Gloucester, received his medical education at Bristol and University College Hospital, taking at the former school several prizes and scholarships in medicine and surgery. He obtained the qualifications of L.R.C.P. Lond. and M.R.C.S. Eng. in 1881 and 1880 respectively and in 1892 that of D.P.H. of the Royal Colleges of Physicians of London and Surgeons of England. Major Marsh had seen nearly 18 years' service in the army and previously to his illness was principal medical officer at De Aar. He saw active service in the Burmese Expedition of 1885 to 1887 when he was in medical charge of a battery of mountain artillery and was present in several engagements near Ningyan and Yemethen, and in the latter place during its investment in 1886. For this campaign Major Marsh received the medal with clasp. The deceased leaves two brothers, one of whom, Mr. O. E. Bulwer Marsh, M.R.C.S. Eng., L.R.C.P. Lond., J.P., is in practice in Newport, and the other, Mr. Earle Marsh, was recently high sheriff for Monmouthshire.

FRANCIS JOSEPH MATHEWS, L.R.C.P., L.R.C.S. IREL.

MUCH popular sympathy was manifested by all classes on the occasion of the death of Mr. Mathews of Cavan, which occurred on May 21st, after a very short illness. The deceased gentleman received his professional training in the schools of the Royal College of Surgeons in Ireland and acquitted himself so creditably as a student that he gained a medal in the class of Materia Medica and Therapeutics. In 1894 he was admitted a Licentiate of the Royal Colleges of Physicians and Surgeons in Ireland and eventually settled in Cavan, where he was appointed medical officer of the Stradone Dispensary District and medical attendant to the Royal Irish Constabulary. Of a fine presence and affable manners he endeared himself to a large circle of friends and acquaintances and won the confidence of all those with whom he had professional relations. The cause of his death was tetanus originating in a wound of the right leg sustained in a bicycle accident about May 10th. The funeral took place in Laragh graveyard on May 23rd, a requiem mass having been previously celebrated in Cavan Cathedral.

THE School Board for London have appointed Robert J. Collie, M.D. Aberd., medical superintendent of the Board's ambulance and home nursing classes. The number of pupils who received instruction in ambulance and home nursing last winter was close on 10,000. The Board have decided that all ambulance classes shall be taught by medical men assisted by the Board's teachers. The course consists of 12 lectures, and these will be given alternately by the medical man and the Board's teacher. The fee has been raised to a guinea per lecture. We understand that until recently the pupils were presented for examination by the St. John Ambulance Association, but that the Board have now determined in future to grant their own certificates.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE Council continued to sit throughout Wednesday and Thursday, and the proceedings will be reported as usual in full in our columns next week.

On Wednesday a motion by Mr. Brown that the Registrar should send to every registered medical practitioner in the United Kingdom a copy of the Council's resolution of June 6th, 1899, with regard to medical aid associations was withdrawn, the intent being foreshadowed by Sir John Batty Tuke to introduce at a future session a stronger resolution. Mr. Brown's was a useful motion, but his object will have been served if the Council is led in the near future to make a clear pronouncement to the registered practitioners upon the subject.

On the same day, on the motion of Sir Dyce Duckworth, the General Medical Council received the recommendation of the Examination Committee expressing the opinion that another cycle of inspections of final examinations of the several universities and examining boards should be begun during the present year.

On the motion of Sir John Batty Tuke, seconded by Dr. MacAlister, a further report by the Education Committee on the question of raising the standard of the preliminary examination in general education was received and entered on the minutes. The report showed that a substantial advance on the present regulations could be made by insisting on improvements in the character and stringency of the junior examinations which could be directly influenced by the Council; and the same advance could be secured in the case of other examinations by requiring that candidates offering corresponding certificates should have obtained a higher standard than that of a simple pass.

The recommendation of the Education Committee fixing a limit of age below which an applicant shall not be allowed to register as medical or dental student was adopted by the General Medical Council who placed the age at 16 years; consequently, from and after Jan. 1st, 1902, no person will be registered as a medical or dental student who has not attained the age of 16 years.

The report of the Pharmacopœia Committee was received and adopted, the Council recording their cordial thanks to Dr. Leech, Mr. Bryant, Mr. Ekin, and Dr. Walter Hills for important contributions which they had secured to the Pharmacopœia library.

THURSDAY, MAY 24TH.

IN THE LANCET of May 26th we reported the proceedings of the first two days of the session of the Council and resume now with the third day. Sir WILLIAM TURNER, as usual, occupied the presidential chair.

Restoration to the Medical Register.

The PRESIDENT announced, after the Council had been sitting *in camerâ* for a time, that it had been resolved to restore to the Medical Register the name of George Ingersoll Curragh, who possesses the Licence of the Society of Apothecaries of London.

The Case of William Matthews Joyce.

The first business on the programme of the day was the consideration, adjourned from Dec. 1st, 1899, of the charges proved against William Matthews Joyce, registered as of 25, Cattell-road, Small Heath, Birmingham, with the triple qualification of Scotland, 1889, who had been summoned to appear before the Council on the following charges: (*a*) that he was, on July 10th, 1899, at the Warwick Borough Sessions, convicted of being drunk and disorderly; and (*b*) that he was, on Nov. 13th, 1899, at the Warwick Court-house, convicted of misdemeanour—namely, of assaulting and beating Ellen Simpson. At the conclusion of the deliberations of the Council on this case, on motion made from the chair, it was resolved: "That the further consideration of the case of William Matthews Joyce be adjourned till the May session of the Council."

Mr. Joyce appeared in answer to his name.

The PRESIDENT, addressing him, said: You know, Mr. Joyce, the charge made against you at the previous session of the Council. Have you sent in any certificates?

Mr. JOYCE: No; I have none.

The PRESIDENT: Have you anything to say?

Mr. JOYCE: Nothing; I stand here exactly as I stood before.

The PRESIDENT: Has your conduct since you were here last been what it should have been? Has your conduct been altogether correct?

Mr. JOYCE: With great respect I think that matter is for the Council.

The PRESIDENT: I ask you the question.

Mr. JOYCE: I have done nothing to bring me into court at all.

The PRESIDENT: Has your conduct since you were here last been the conduct which you as a member of the profession ought to exhibit?

Mr. JOYCE: Yes; it has been just as my father would recommend, and he was a medical man.

The Council then deliberated *in camerâ* on the case, and when Mr. Joyce was readmitted to the hall the PRESIDENT announced to him that the Council had directed the Registrar to erase his name from the Medical Register.

The Case of James Alexander Graydon.

The Council proceeded to the consideration of the case of James Alexander Graydon, of 21, South-grove, Bow-road, E., registered in Ireland Dec. 7th, 1872, as Lic. Fac. Phys. Surg., Glasgow, 1870, who had been summoned to appear before the Council in consequence of his conviction on March 5th, 1900, at the Thames police-court, for assaulting his wife and his sentence to pay a fine of 21*s.* or go to prison for seven days with hard labour.

Mr. FARRER, jun., read to the Council a certificate of the conviction and sentence. He also read a letter from Mr. Graydon, in which he said he was intoxicated when he struck his wife and was extremely sorry for his action, and he had been a total abstainer for 10 weeks and intended to continue one. Mr. Farrer also read a letter from the wife pleading for lenient treatment for her husband.

Mr. GRAYDON, in answer to the President, said he was extremely sorry for what he had done. He had taken the pledge and he meant to keep it.

After the Council had deliberated in private for a time

The PRESIDENT, addressing Mr. Graydon, said: The Council have given a careful consideration to your case. They are willing to give you an opportunity of redeeming yourself and they will require that you should appear here at the November session and the Council will expect you to produce evidence when you reappear that your conduct and character have been satisfactory in the interval between now and the November session. And in order to do that they will call upon you to produce written certificates from responsible persons. They would like that at least one of your certificates should be from a medical practitioner who knows you and the certificates must bear that your conduct and character have been entirely satisfactory during the interval between now and the month of November.

The Inspection of Documents.

The Council granted liberty to Mr. Horsley to inspect the accounts of the solicitor to the Council for 1899.

The Case of Dr. Robert Herbert Foot.

The Council next proceeded with the case of Robert Herbert Foot, of 6, Elliot-road, North Brixton, S.W., registered in Ireland Dec. 23rd, 1872, as Lic., Lic. Midwif., 1872, R. Coll. Surg. Irel.; M.B. 1872, M.D. 1874, Univ. Dubl.; who had been summoned to appear on conviction for misdemeanour committed in Clapham-road, Lambeth, on April 6th last, and for which he was sentenced to three months' imprisonment with hard labour.

Dr. Foot attended in answer to his summons, together

with his counsel, Mr. Eldon Bankes, and his solicitor, Mr. H. Walter Nelson, of the firm of Lowless and Co.

Mr. FARRER, jun., read the summons and the certificate of conviction and other documents in support of the charge.

Mr. ELDON BANKES then read the statutory declarations for the defence. He also handed in the depositions which had been taken at the police-court and then addressed the Council on behalf of Dr. Foot. He explained that Dr. Foot was convicted on a misapprehension due largely to his own fault in refusing, when accused and on trial, to communicate with his friends and to have professional legal assistance and medical evidence that would have shown, as counsel said he would do later, that his unfortunate client while suffering from illness of some years' existence had been the victim of a mistake. Counsel had not heard till now that Dr. Foot's friends in Ireland had petitioned the Home Secretary for a commutation of sentence on the ground that the alleged offence had been committed while he was temporarily insane.

Mr. R. PATRICK WALL, a neighbouring practitioner, said that what he had stated in regard to Dr. Foot's illness was true. He had known Dr. Foot for eight or nine years.

Dr. FOOT, who was called on his own behalf, was questioned by several members of the Council as to his illness, and he said that he would like to remove all idea of his being insane. He was no more insane than the usual persons who were outside of an asylum.

Mr. WALTER NELSON, a partner of Messrs. Lowless and Co., was called to prove the receipt from Mr. Cameron, solicitor, Dublin, who had acted for Dr. Foot's friends, of a copy of the memorial forwarded to the Home Secretary.

After the Council had deliberated *in camerâ*

The PRESIDENT said: Dr. Foot, the Council have very carefully considered all the circumstances connected with your case and they do not direct the Registrar to erase your name from the Register.

During the consideration of this case ladies were asked to withdraw.

The Case of Armitage Forbes.

The next business was consideration of the case of Armitage Forbes of 28, Charlotte-street, Ashfield, Sydney, New South Wales, registered in Ireland, Feb. 12th, 1879, as Lic. R. Coll. Surg. Irel. 1878; Lic. R. Coll. Phys. Edin. 1879; who had been summoned on the complaint of the Queensland Medical Board on the following charges formulated by the Council's solicitor:—

1. That he was associated and connected with an institution calling itself the Anglo-Australian Medical Institute as one of its directing staff, which institute publicly advertises systems of medical treatment and remedies for particular diseases and seeks to attract patients by the advertisement of such treatment and remedies, and that he was a party to the publication of the advertisements of the said institute and its treatment and remedies, and of his name, address, and qualifications as a British registered medical practitioner in connexion therewith.
2. That the advertisements and the system of advertising to which he was a party were in themselves of such a character that it was discreditable in a British registered medical practitioner to be connected with them.
3. The advertisements above referred to were contained in pamphlets, cards, and leaflets purporting to be issued by the said Anglo-Australian Medical Institute, Queen and Edward Streets, Brisbane, and in issues of newspapers circulating in the colony of Queensland named *The Queenslander*, *The Brisbane Courier*, and in the issues of other newspapers and in other publications in the said colony.

Mr. FARRER, jun., read the summons and the documents in support of the charges.

Mr. Forbes did not appear, but two letters from him were read to the Council. In the first of these he wrote that advertising was necessary in Sydney in order to assure the public that the institute with which he was connected was not carried on by quacks. Medical men practising in New South Wales advertised both in town and country and he wished to be informed as to what constituted a breach of professional etiquette. In the second letter he wrote that he was not aware till he had received information from the Registrar that what he had been doing would be regarded by the General Medical Council as infamous conduct in a professional respect. He could state positively that no kind of unorthodox or illegitimate practice took place in the institute, but he admitted that his name, which had never appeared publicly in any newspaper advertisement, was attached to various pamphlets issued by the institute. He regretted very much that he had incurred the displeasure of the Council and since getting notice from them the institute had been closed, directions had been given to discontinue all advertisements, and he had apologised to the Queensland Medical Board. He had done what he could to atone for his fault and he would not offend in future. He trusted the Council would not have recourse to such a serious measure as striking his name off the Register.

In answer to the PRESIDENT it was stated that no communication from the Queensland Medical Board confirming the statements in the second letter from Mr. Forbes had been received at the Council's offices.

The PRESIDENT said that perhaps the Queensland Medical Board had not had time to communicate with London and he questioned whether it would not be advisable to send a copy of Mr. Forbes's letter to Queensland and adjourn the case till the November session to get a reply corroborative or otherwise.

After some discussion

Mr. HORSLEY asked if it would not be fitting that the President should put the question to the Council. They were all agreed with him.

Dr. MCVAIL was not so sure about that. He contended that the Council should take action that day so as not to allow Mr. Forbes another six months in which he might further misconduct himself supposing he were guilty of the charges now brought against him.

The PRESIDENT: He has admitted them.

Dr. MCVAIL: Though a man admits a crime it does not necessarily follow that he should not be punished for what he has done.

The Council deliberated on the case in private. On the re-admission of the public

The PRESIDENT said: I have to report that the Council has directed the Registrar to erase from the Medical Register the name of Mr. Armitage Forbes.

The Case of Arthur Oglesby.

The Council proceeded to the consideration of the case of Mr. Arthur Oglesby in regard to which the following report was received from the Dental Committee:—

The complaint against Arthur Oglesby having been referred to the Dental Committee to ascertain the facts the Dental Committee beg to report as follows:—

On Feb. 27th, 1900, the following parties attended before the committee and were duly heard, namely: Hugh Woods, M.D., B.A., the honorary general secretary of the London and Counties Medical Protection Society, Limited, the complainants, and the said Arthur Oglesby. The committee find that the following acts were established by the evidence: (1) that Arthur Oglesby was registered in the Dentists Register on July 10th, 1891, as having been in practice before July 22nd, 1878, and his address in the Dentists Register is 21, Cheapside, Barnsley; (2) that Arthur Oglesby has systematically sought to attract professional practice by the issue of public advertisements of his name, address, appliances, and professional qualifications; (3) that in particular he advertises himself as D.D.S. University Ill., which alleged diploma he admits that he obtained without visiting America or being subjected to any examination; (4) that the public advertisements issued by Arthur Oglesby are highly objectionable; and (5) that Arthur Oglesby states that since the month of September, 1899, he has discontinued the issue of the advertisements which were brought before the committee. But he continues to advertise himself by the issue of an objectionable card in the local newspapers.

The evidence before the committee consisted of the following: 1. The statutory declaration of Dr. Hugh Woods and the advertisements therein referred to. 2. The oral statement of Arthur Oglesby and the advertisements referred to by him and transmitted by Arthur Oglesby to the Council. 3. The following documents: Letter of complaint by Dr. Woods dated August 10th, 1899. Letter from the Registrar of the General Medical Council to Arthur Oglesby dated Sept. 12th, 1899. His reply of Sept. 13th, 1899. Further letters from him to the Registrar of Dec. 2nd, 1899. The like of Jan. 19th, 1900. Paragraph from THE LANCET and specimens of advertisements referred to by Arthur Oglesby. Letter to the General Registrar dated Jan. 29th, 1900, and the newspaper extract enclosed therewith.

WM. TURNER, chairman.

The PRESIDENT pointed out that this report must be taken as conclusive with regard to the facts, and what the Council had now to determine was whether it would deal at once with the report or hear parties to the inquiry upon the report or any question arising upon it.

On a vote being taken it was decided by 13 to 2 to hear parties.

Mr. OGLESBY availed himself of the opportunity that this vote afforded him. He said that before September last he had no idea that he was doing wrong. Although he had advertised for years he did not advertise in a way that he at least thought was objectionable—that was to say, in the way of exhibiting appliances or show-cases, stating prices, or as having a secret process. And he wished to say that in England a man was generally cautioned before he was brought up before a tribunal like the General Medical Council, but he had never had the slightest caution or remonstrance before being called upon in November last to answer the charge. That did not seem a generous action

on the part of such a body as this. He did not think he had much to say about the report. With reference to that paragraph in it which stated that he had systematically sought to attract practice by the issue of public advertisements of his name, address, appliances, and professional qualifications he wished to emphasise his statement that he had not exhibited any appliances or show-cases or anything of that sort. He wished also to say that when he got the notice from the General Medical Council he ceased to use the advertisements complained of and simply used a business card. If the committee must regard the card as objectionable every advertisement in the land was such, and if a person was not permitted to use such a card as his no man who was a dentist should be allowed to advertise in the future, so that dentists might know where they were. With regard to the next paragraph he had to say that he obtained the degree referred to there upon the production of proofs of his knowledge and skill. He had no wish to go against the General Medical Council in any way and he was prepared to submit to anything that they considered just.

The PRESIDENT: Did you not receive the Council's notice to dentists in regard to this matter?

Mr. OGLESBY: Not the slightest caution.

The PRESIDENT: Did you receive the notice from the Council relating to the issue of advertisements by dentists as objectionable?

Mr. OGLESBY: I did receive that notice and so soon as I received it my advertisements ceased.

Mr. TEALE: Did you discontinue all advertisements?

Mr. OGLESBY: Except the card.

Mr. TEALE: What about the large advertisement on the house, the whole end of which was painted up?

Mr. OGLESBY: I never thought of that. It continues. There is nothing objectionable on it—only my name and address.

Dr. GLOVER: Simply your name and address?

Mr. OGLESBY: I think that is all. It is three or four years since it was done, and if there is any more it can be only two or three words.

Dr. HERON WATSON: You say you are D.D.S. Did you pay for it?

Mr. OGLESBY: Yes, sir; every degree is paid for.

The PRESIDENT: Oh, no.

Dr. GLOVER: Were you examined for it?

Mr. OGLESBY: No, sir; I sent proofs of my skill and knowledge.

Sir DYCE DUCKWORTH: You have never been in the United States?

Mr. OGLESBY: No, sir.

Dr. LITTLE (looking at Mr. Oglesby): It seems an extraordinary thing to believe that he has been in practice since 1878—that is 22 years. May I ask what his age is?

Mr. OGLESBY: My age is 38 years.

The PRESIDENT: Then do we understand that you were in practice at 16?

Mr. OGLESBY: I was in practice when I was 12 years old.

Dr. MACALISTER: Independent practice?

Mr. OGLESBY: Oh, no.

Dr. WOODS, who was then asked if he had anything to say upon the Dental Committee's report, said that the only point on which he would like to speak was on the matter of dental advertising. He agreed with Mr. Oglesby that it was time dentists should be clearly informed whether or not advertising by them was infamous conduct in a professional respect. That Mr. Oglesby had been selected to answer to the General Medical Council was no fault of his. Advertising by dentists had reached almost the lowest depths of advertising by any trade whatever and it was absolutely necessary that it should be put a stop to. The only way in which this might be done was by presenting a concrete case and he hoped the Council would not allow any consideration to interfere with their pronouncement that advertising of an objectionable character was infamous conduct in a professional respect.

Dr. MCVAIL: Does Dr. Woods consider this man as only representative of a class or does he regard him——

The PRESIDENT: Order, order. That is not a matter that we can go into with Dr. Woods.

The Council then sat *in camerâ*. On parties being recalled

The PRESIDENT said: The Council, Mr. Oglesby, have given very great consideration to your case and they have come to the resolution that your name is to be removed from the Dentists Register.

The decision in this case, as Mr. Tomes stated, the first of its kind, is recorded officially in the following terms:—

(*a*) That the Council do proceed at once to pronounce its judgment on the case.

(*b*) That on the facts found in the report of the Dental Committee it has been proved that Arthur Oglesby has been guilty of conduct which is infamous or disgraceful conduct in a professional respect.

(*c*) That Arthur Oglesby having been proved to have been guilty of infamous or disgraceful conduct in a professional respect the Council do direct the Registrar to erase from the Dentists Register the name of Arthur Oglesby.

The Council adjourned.

FRIDAY, MAY 25TH.

The Council met again to-day, Sir WILLIAM TURNER being in the chair.

The Case of Owen McBreen.

The Council proceeded to the consideration of the case of Owen McBreen of 59, Mesnes-street, Wigan, a dentist registered on Nov. 28th, 1878, as "in practice before July 22nd, 1878." The complaint against Owen McBreen having been referred to the Dental Committee to ascertain the facts, the Dental Committee reported as follows:—

On April 26th, 1900, the committee met to ascertain the facts, when Mr. Owen McBreen appeared in person and not accompanied by a solicitor or witnesses. The committee find that the following facts were established by the evidence and admission of Mr. McBreen. That Owen McBreen being a dentist registered in the Dentists' Register as in practice before July 22nd, 1878, and possessing no other registrable qualification, and not being a Licentiate or Member of the Royal College of Surgeons of England, Ireland, or Edinburgh, or any of such Colleges, habitually published advertisements in which he described himself as R.D.S.E. (registered by Royal College of Surgeons), thereby causing it to be inferred that he is connected with one of the Royal Colleges. Mr. McBreen apologised for the offence which he had committed, and promised not to repeat it.

The evidence before the committee consisted of the following:—(i.) A letter from the Assistant Secretary of the Royal College of Surgeons of England to the Registrar of the General Medical Council, dated Jan. 17th, 1900. (ii.) A print of the advertisement referred to in such letter. (iii.) A letter from the Registrar of the Royal College of Surgeons in Ireland to the Registrar of the General Medical Council, dated Jan. 23rd, 1900. (iv.) A letter from Mr. James Robertson, Clerk of the Royal College of Surgeons, Edinburgh, to the Registrar of the General Medical Council, dated Jan. 25th, 1900. (v.) The admission of Mr. McBreen that he published the advertisements complained of.

Mr. MCBREEN, addressing the Council, said he laid the blame for what had occurred upon the printer of the church magazine in which the advertisement appeared; but while he did so he accepted responsibility for himself, said he was sorry for the mistake, and undertook that it would not happen again.

Dr. GLOVER: What did you mean to imply by the letters R.D.S E.?

Mr. MCBREEN: Registered dental surgeon.

Dr. GLOVER: Of what?

Mr. MCBREEN: Of England.

Dr. ATTHILL: Are we to assume that the words "registered by Royal College of Surgeons" were inserted in the advertisement by the printer?

Mr. MCBREEN: I believe they were.

Dr. GLOVER: How did these words come to be in the advertisement?

Mr. MCBREEN: They cannot be found in any advertisement since. The printer may have seen them somewhere and put them in by mistake.

After the Council had deliberated *in camerâ*

The PRESIDENT, addressing Mr. McBreen, said: I have to tell you that after very careful consideration the Council have found that the facts stated in the report of the Dental Committee have been proved against you, and that you are guilty of conduct which is infamous or disgraceful in a professional respect, and I have further to say to you that in consequence of this the Council have directed the Registrar to erase your name from the Dentists Register.

The Case of Charles Louis Lumley.

The Council then considered the case of Charles Louis Lumley of 1, Jermyn-street, St. James's, S.W., registered in England June 7th, 1882, as Lic., Lic. Midwif., 1881, R. Coll. Phys. Irel., who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That he was guilty of practising a fraud upon a Mr. Balmer by sending in to him and demanding payment of an account of charges for medical attendance and services rendered to Mr. Balmer's wife when as a fact he had not attended or seen or known Mr. Balmer's wife during the period or any part of the period included in the account; which account was sent in by him with the intention of deceiving Mr. Balmer into the belief that he had professionally attended upon his

(Balmer's) wife and in order to induce him to pay the amount of his pretended charges.

Mr. Lumley attended in answer to his summons, together with Mr. Roskill, his counsel, instructed by Messrs. Cooper and Bake, his solicitors.

Mr. FARRER, jun., explained that the case was the outcome of certain proceedings in the Divorce Court in which Mr. Lumley was a co-respondent. He then read to the Council a transcript of evidence given by Mr. Lumley, in the course of which the latter said he had met Mrs. Balmer at a cycle school, but had never treated her professionally. The proceedings in the Divorce Court were on July 23rd, 1897. He gave Mrs. Balmer a bill for medical attendance between November, 1895, and May, 1896, a bill for £19 10*s*. He understood from Mrs. Balmer that her husband would pay nothing towards her maintenance but for sickness, and Mrs. Balmer said that there was money owing for this period and asked him if he would be good enough to put his name to the bill. He denied that he had written two letters to the husband demanding payment; at any rate, he did not remember having done such a thing. If he had done it then it must have been out of sympathy with Mrs. Balmer.

Mr. ROSKILL, addressing the Council for Mr. Lumley, said that this inquiry was confined to matters arising out of the charge formulated against his client. He admitted at once that Mr. Lumley's conduct had been indiscreet. As to the allegation that his client demanded in two letters payment of the bill he insisted that it had no foundation, and further, he pointed out that the two letters had not been produced—indeed, he was satisfied that the letters had never existed. The relation of doctor and patient never subsisted between Mr. Lumley and Mrs. Balmer. What the latter told the former was that she was in distress and could only get assistance from her husband by telling him that she was ill. She had been ill, but had been so before Mr. Lumley knew her. After repeatedly refusing Mrs. Balmer's request that he should make out a bill for her he at last was prevailed upon, but no sooner had he made out the bill than he realised the mistake into which he had fallen. Next day he went to Mrs. Balmer and demanded the bill back or that it should be destroyed. Mrs. Balmer told him that she had not posted it, and after professing to look for it she said it could not be found. Later on she informed him that it had been found and duly destroyed, and it was a great surprise to Mr. Lumley to find the bill produced in court. It was untrue that Mr. Lumley ever wrote to the husband asking payment of the bill. Counsel went on to argue that in this case the man as a member of society must be distinguished from the man as a medical practitioner, and that Mr. Lumley could not be held as coming under Section 29 of the Medical Act of 1858. He quoted from a decision of the late Master of the Rolls who, in giving judgment in a case he tried, laid it down that if it was shown that a medical man in the pursuit of his profession had done something with regard to it which would be reasonably regarded as disgraceful or dishonourable by his brethren of good repute and competency then it was open to the Medical Council to say that he had been guilty of infamous conduct in a professional respect. That gave a definition of infamous conduct in a professional respect. It laid it down that infamous conduct must be between a medical man and his patient or between a medical man and his professional brethren. He was not seeking to palliate the conduct of a man who told a lie or did a dishonourable action. Mr. Lumley admitted that when he gave the bill to Mrs. Balmer he did do a dishonourable action, but it was not done towards a patient, and if the Council believed what Mr. Lumley had said was the truth they must find that what he had done was not infamous conduct in a professional respect. If a man did a dishonourable action or something else for which he could not be convicted in a public court consequences under the Medical Act could not follow. If Mr. Lumley was not speaking the truth when he denied asking payment of the bill from Mr. Balmer he was none the less outside the scope or Section 29 of the Act, for if he had committed a criminal offence the General Medical Council could intervene only on conviction for it.

Mr. LUMLEY was tendered as a witness on his own behalf and bore out his counsel's statement of the facts. He was asked if Mrs. Balmer ever was a patient of his, and he replied that she was not; he had never attended her professionally. He had tried to find her since the divorce proceedings, but he had never been able to discover any trace of her whatever. He never had written to Mr. Balmer. He knew there was a Mr. Balmer, but he never knew his address, he had no idea of his whereabouts or what he was. He never was alone with Mrs. Balmer and never had committed adultery with her. When he was confronted with the bill during the divorce proceedings he was astonished. His counsel in the case knew nothing about it, and until he (witness) was in the witness-box he had no other idea about it than that it had been destroyed.

Questioned by Mr. HORSLEY in order to have an explanation as to the interval of time that had elapsed between the divorce case and the action taken by the General Medical Council, Mr. Lumley stated that his name had lapsed; it had been off the Register for two or three years because he was travelling about a good deal and could not send the Registrar a fixed address. The name had been put on the Register again in January of the present year.

By Dr. GLOVER: The bill given to Mrs. Balmer was made out by himself and was on the usual printed form.

By the PRESIDENT: So far as he could recollect the bill was made out to Mr. Balmer.

By Dr. LITTLE: The bill was filled in in the evening at Mrs. Balmer's house.

How did it happen that you had one of your account forms at her house?—She had previously asked me for the account. She never was in my house.

By Sir JOHN BATTY TUKE: Mr. Balmer was the first witness at the divorce trial.

In connexion with the letters you were said to have written him was there any corroborative evidence?—He never made any reference to the letters. They were put in by his solicitor.

Sir J. BATTY TUKE: Why was Mr. Balmer not recalled?

Mr. ROSKILL: It was a shame that he was not recalled. It is a strong point in Mr. Lumley's favour that he was not.

By Mr. TOMES: He gave the bill to Mrs. Balmer after he had been acquainted with her for about 11 days. He was not to receive anything out of the money, and he had no idea what the woman would do with it if she got it. He got no money from her.

By Dr. GLOVER: She had previously asked for the bill on the evening she got it. He had gone and fetched the bill-head. It was done on the spur of the moment.

The PRESIDENT: Are we to understand that supposing Mr. Balmer had paid the £19 10*s*. it would have been paid to you?

Mr. LUMLEY: Oh dear, no.

The PRESIDENT: But the account was made out as money due to you; if Mr. Balmer had acknowledged the account would he not have paid you?

Mr. LUMLEY: I understand that he would have sent the money to her. He always, she said, sent the money to her.

The parties were then asked to withdraw. On their being recalled,

The PRESIDENT announced the decision of the Council. Addressing Mr. Lumley, he said: The Council has given a very careful consideration and inquiry, as you know, to your case, and the resolution they have come to is that they direct the registrar to erase your name from the Register. That is the judgment.

Mr. LUMLEY: I regret it exceedingly. Would there be any chance of its being introduced again? It is taking away from a man his chances of earning his livelihood when he is getting up in years.

The PRESIDENT: That is a matter on which we cannot give an opinion now. If you apply to the registrar he will let you see the standing orders.

Mr. Lumley withdrew.

The Council dealt partly with the next case on the programme—that of Mr. Andrew Alexander—before rising for the day.

SATURDAY, MAY 26TH.

The Council resumed to-day, Sir WILLIAM TURNER, the President, being in the chair.

The Case of Andrew Alexander.

Consideration was given to the case of Mr. Andrew Alexander of Blaydon-on-Tyne, registered in Scotland, Sept 5th, 1885, as Lic. R. Coll. Phys. Edin., 1885; Lic. R. Coll. Surg. Edin., 1885; Lic. Fac. Surg. Glasg. 1885, who had been summoned to appear before the Council on the complaint of the Gateshead Medical Association on the following charge as formulated by the Council's solicitor:—

That, being a registered medical practitioner, he covered an unqualified person named Tait whom he employed or purported to employ as an unqualified assistant, and whom he permitted and enabled to attend

on and administer medical relief to patients and carry on medical practice as if he were a duly qualified practitioner.

Dr. BATEMAN, as representing the Medical Defence Union and the Gateshead Medical Association, appeared in support of the complaint.

Mr. Alexander attended in answer to his summons, together with his counsel, Mr. Horridge, instructed by Messrs. Rowcliffes, Rawle and Co. (represented by Mr. Lean).

Mr. FARRER read the summons.

Dr. BATEMAN opened the case for the complainants. He stated that as soon as Mr. Alexander employed Tait steps were taken to warn him that he was not acting in conformity with the Council's prohibition of the employment of unqualified assistants. Tait wrote in reply that Mr. Alexander had decided to run the risk and that if he did so it was no concern of the giver of the warning. Mr. Alexander stated in a letter he wrote that when he entered into an agreement with Tait he made no inquiry into the latter's medical training because he saw that pupils were allowed, and it was as a pupil that he had Tait with him. Mr. Tait, Dr. Bateman observed, had not even entered upon studies in a hospital. Mr. Alexander had been brought into the district by the miners themselves in opposition to the resident medical men, and it was impossible to get any of the miners to appear against him.

Mr. ALFRED COX (Gateshead) was then called as a witness. He proved the truth of a statutory declaration made by him in March last. In this he stated that he was told that Mr. Alexander had employed an unqualified assistant and as secretary of the Gateshead Medical Association he had made inquiries. He saw Tait at Mr. Alexander's business place. Tait was referred to by the door attendant as "doctor," and he admitted that he was not qualified, but said he hoped soon to go to college.

Questioned by Mr. HORRIDGE, Mr. COX said that Mr. Galloway and Mr. Davis made the complaint. They attended the miners before Mr. Alexander came to the district. He never saw Mr. Alexander.

No questions were put by members of the Council.

Mr. WILLIAM HENRY DAVIS (Gateshead) was next examined by Dr. BATEMAN. His evidence was to the effect that Tait was said to have attended families and prescribed for them, but there was great difficulty in getting evidence. Many of them did not know that Tait was unqualified.

Mr. HORRIDGE objected to the admission of the last statement unless it was to be confirmed by the oral testimony of witnesses.

Mr. DAVIS, in answer to further questions by Dr. BATEMAN, stated that the practice he held had been in the family for about 100 years. Before Mr. Alexander came there was considerable feeling in the district about the payments by the miners to the medical men. The latter desired that their fees should be raised, and so soon as they were raised advertisements had been issued for a medical man to attend the men employed at certain of the collieries. Asked if there was any difficulty in getting qualified assistants he replied that he had two qualified assistants.

Asked by Mr. HORRIDGE if there was in attendance anyone who could be cross-examined in corroboration of the statement that many did not know that Mr. Tait was unqualified, he replied that he did not know that a defence of such a kind was to be set up.

Mr. HORRIDGE said that it was not a defence but a charge against Mr. Alexander.

Mr. DAVIS admitted that when Mr. Alexander came into the district he interfered very much with Mr. Davis's practice. Asked if he had gone about the place saying that Mr. Alexander was a "blackleg" he replied that he did not say he was a "blackleg" in the ordinary meaning of the common term as used in the north of England. By "blackleg" he meant a man who undersold others for the benefit of himself. He did not know that pressure had been brought to bear on Mr. Thomson, the qualified assistant Mr. Alexander got soon after he entered the district, so as to make him leave Mr. Alexander.

Mr. JOSEPH CHARLES DOVER, commercial traveller, Gateshead, was also examined. He said that acting on instructions he had gone to Mr. Alexander's business place and asked for the "doctor." He was shown into a room and saw a young man of 22 or 23 years of age. Witness asked him if he was Dr. Alexander and he replied, "No; I am his assistant." Witness consulted him as to pains in the back and liver, and the young man gave him medicine and charged him 2*s.* 6*d.* He got a certificate from him out of a book. This was signed "A. Alexander." He noticed that there was a similarly signed certificate underneath. The young man told witness to look in again and to ask for the assistant. At that time he had no pains in the back or liver. He had gone to Mr. Alexander's place with the intention of finding out whether this man Tait was in practice.

Mr. HORRIDGE did not cross-examine.

In answer to Dr. MACALISTER, the witness said that Tait did not tell him what he was suffering from.

Dr. BATEMAN put in the certificate given to Dover, which was signed "A. Alexander," and read: "This is to certify that J. C. Dover is under my care suffering —— and is unable to follow his employment." He also put in correspondence between Mr. Alexander and himself. Mr. Alexander's letter stated that Tait was his pupil and he allowed him to watch the development of disease and its treatment and try his own hand in the management of trifling ailments. He (Mr. Alexander) attended at the surgery where Tait was engaged every day except Sunday. He himself saw all fresh cases and all cases of a serious nature. Dr. Bateman also put in a declaration made by Mr. Walter Galloway, L.R.C.P. & S. Edin., who was, he said, unable to attend.

This closed the case in support of the complaint.

Mr. HORRIDGE addressed the Council on behalf of Mr. Alexander. He said that directly the Council's resolution on the subject of unqualified assistants was shown to Mr. Alexander he had told the latter that he believed he had committed a breach of the regulations, but he wished to put before the Council the exact circumstances in which that had taken place. The engagement with Tait had not been made in any way in bad faith, and Mr. Alexander would undertake to at once send away the pupil whom he had kept on pending the present inquiry. The dispute between the miners and the medical men of the district had occurred last year. The fees were raised from sixpence a fortnight to ninepence, and as the miners thought they had been treated in an offhand manner they had come to Mr. Alexander and in many cases that gentleman was getting the 9*d.* Nobody except Mr. Galloway and Mr. Davis had complained. When Mr. Alexander entered upon the practice he got Mr. Thomson to assist him. This man was qualified and came for a month's trial at £200 per annum, but within the month he left for no reason at all. Mr. Alexander advertised for another assistant, but so strong was the opposition that he could not get a qualified man. The difficulty of getting qualified men became very great after the issue of the Council's resolution on the subject, but from September last the difficulty had been accentuated by the number of qualified men going to the war. Mr. Alexander had done his best to get a qualified man, and when he got hold of a cutting from a medical journal which he read as meaning that he could employ a pupil who was not at the same time a *bonâ fide* medical student he took Tait, and thought he was doing right so long as he, being himself a registered medical practitioner, supervised him. There had not been one bit of concealment from first to last as to what Tait's position was. In conclusion, counsel submitted that the case was one that should not be severely dealt with.

Mr. ALEXANDER was tendered as a witness on his own behalf. He stated that when he went to Gateshead in the beginning of 1899, a good deal of friction arose between him and the other medical men in the district. Mr. Thomson had left him in September and there was not the slightest reason for his going away. If he had stopped, the terms offered him would have made his position worth £250 a year. Witness had taken Tait in the circumstances and on the conditions which counsel had explained, and there was not a word of truth in the suggestion that Tait was held out to be qualified. He had frankly admitted publicly everywhere that Tait was unqualified, and he had never even suggested that he was a student. With regard to the certificate put in he found it necessary to keep a book of certificates signed.

Questioned by Dr. BATEMAN he admitted that he had been carrying on the practice with Tait as a pupil.

What did Tait pay for taking him as a pupil?—He paid nothing. I gave him board and lodgings and paid him for confinements 5*s.* each case.

The PRESIDENT: You have a written agreement with Mr. Tait. Is it here?

Mr. HORRIDGE: It is not.

By Sir DYCE DUCKWORTH: I think Tait is about 22 years of age.

By Dr. LITTLE: He was employed to do easy midwifery. He went to the Maternity Hospital in Glasgow and saw 20 cases there and I took him to a good many cases.

By Dr. BRUCE: Has he ever used forceps?—Never.

By Sir HECTOR CAMERON: Did he represent himself to the authorities of the Glasgow Maternity Hospital as a registered medical student?—I believe he represented himself as a pupil of mine. It was after the engagement with me that he went to the Maternity.

Sir H. CAMERON: I think they must have misunderstood that he was a registered medical student or they would not have taken him. That is the rule.

Mr. ALEXANDER: I told Mr. Tait to say that he was a pupil. I told him that unless he could get a good deal of practice in midwifery I could not keep him.

By the PRESIDENT: He took no written credentials with him.

By Mr. HORSLEY: He had obtained Mr. Tait through a gentleman who sometimes acted as his locum-tenent, and who hearing of his difficulty had suggested that he should employ Mr. Tait, his (the locum-tenent's) brother-in-law.

Replying to further questions witness said that he did not say that Tait had seen 22 cases of labour in the Glasgow Hospital. Tait had been at the hospital for a fortnight.

By Dr. GLOVER: He had acquiesced in Tait's going to the Glasgow Hospital in order that he might attend to his (witness's) practice.

Some conversation took place with reference to the print that had misled Mr. Alexander, in the course of which the PRESIDENT expressed the view that it looked more like a cutting from the report of a debate than an advertisement, and Mr. HORSLEY remarked that it was not a copy of the Council's advertisement from either THE LANCET or the *British Medical Journal*.

The Council having deliberated on the case in private

The PRESIDENT, addressing Mr. Alexander, said: The Council have given very careful consideration to the charge that has been made against you and they have come to the conclusion that the charge has been proved to their satisfaction, and they have come to the further resolution that the further consideration of the charge against you be adjourned until the next session in November. The signification of that is this, that you will have to appear here next November and give satisfactory evidence to the Council that you have ceased to employ an unqualified assistant and that your conduct and character between this day and the day when you re-appear have been to the entire satisfaction of the Council.

Proceedings in Camerâ.

The remainder of the sitting was spent *in camerâ* dealing with reports from the Penal Cases Committee and the Special Finance Committee.

MONDAY, MAY 28TH.

The Council resumed work to-day, Sir WILLIAM TURNER being again in the chair.

The Prevention of Personation.

The first business was the adjourned consideration of the report by the Committee on the Prevention of Personation.

The Council having gone into committee of the whole Council,

Mr. HORSLEY, seconded by Dr. BRUCE, moved the adoption of the first recommendation of the committee which was in the following terms, viz.:—

That in all cases where application is made for registration on the Students Register or Medical or Dental Registers under exceptional circumstances the facts of the case shall be furnished in the form of a statutory declaration.

Sir DYCE DUCKWORTH said that this recommendation applied to students and he should like to know whether the hundreds of students who asked to be antedated would require to make a statutory declaration.

Dr. REID said that this appeared to him to be a very cumbrous arrangement and he thought the Council should not adopt it.

The REGISTRAR (Mr. ALLEN) said that if students were brought within the arrangement it would apply to a very large number of cases, and a very heavy responsibility would rest upon the registrars in determining what were exceptional circumstances.

Mr. TOMES said that exceptional cases would be cases which did not follow the usual office routine and such cases he understood were not very numerous.

The PRESIDENT took exception to the proposal to extend the arrangement to students. He thought that the Students Register was already sufficiently protected by the Students Registration Committee who satisfied themselves of the *bona fides* of the certificates. The applications to be antedated came for the most part from students who had received their preliminary training and passed their preliminary examinations abroad and he was afraid it would give them a somewhat painful impression if they were called upon to go before a commissioner for oaths and make a statutory declaration before commencing their professional studies in this country.

Mr. HORSLEY said that all the committee wished to do was to strengthen the hands of the Students Registration Committee.

Sir DYCE DUCKWORTH moved that the words "Students Register or" be deleted from the recommendation, and this was seconded by Dr. REID.

The Council by a large majority decided to strike out these words and the recommendation thus amended was passed.

Mr. HORSLEY moved the second recommendation which was in these terms, viz.:—

With the view to identification of applicants for registration all forms of application shall be filled up in the handwriting of the applicant and in all cases for restoration to the Registers the applicant shall furnish in addition a statutory declaration of the facts of his case as well as a certificate of identity.

Mr. HORSLEY explained that the only alteration proposed in the present state of affairs was that every applicant should be called upon to fill up the application form in his own handwriting.

The PRESIDENT suggested that the recommendation should be divided into two parts.

Mr. HORSLEY agreed to the limitation of his motion to the words, "With the view to identification of applicants for registration all forms of application shall be filled up in the handwriting of the applicant." The three registrars had, he said, issued a note on the proposals of the committee, and he should like to know from Mr. Allen whether he still objected to employing handwriting as a means of identification.

The REGISTRAR (Mr. ALLEN) said that the comparison of handwritings was very useful indeed as corroborative testimony but he failed to see how it could be used as the foundation of a system of registration. The great difficulty was that the Council had not one office but three offices and there was a great deal of cross-registration. For instance, many Scotch students registered ultimately in England. During 1899 there were 43 Scotch students—at any rate, students who obtained their qualifications entirely in Scotland who ultimately registered in England. In such cases there would be no means of comparing the handwriting of the student with the handwriting of the applicant for registration in the Medical Register.

Mr. HORSLEY said he did not understand what the Registrar meant by a foundation of the system of registration. At present the office had no means of identification and he thought the office should be grateful to the committee for the suggestion which they now made. The suggestion meant no trouble for the office; the only trouble was put upon the person seeking registration. The committee could not understand why there should be any hostility on the part of the registrar, and especially when they found that the Scotch registrar had been carrying out this very process all his life.

The REGISTRAR (Mr. ALLEN) disclaimed anything like a feeling to hostility to the proposals of the committee. On the contrary, he should heartily rejoice to receive any scheme which would render personation less possible. His objection to the scheme proposed by the committee was that it seemed to him to be unworkable. The Act said that if a man presented his diploma he was entitled to be registered, and it would be a serious thing to place upon the registrar the responsibility of refusing or deferring registration because he had a doubt in his mind as to the identification of the handwriting.

Mr. BROWN said that if these recommendations were passed the whole system of registration would have to be modified and regulations could be made by which the registrar would be relieved of this responsibility that he dreaded. It seemed to him that the present system opened the door to personation. He thought that if students

registered in Scotland as students and took their course of education in that country and afterwards applied for registration in England as practitioners they should be sent back to Scotland for the purpose of this latter registration.

The PRESIDENT: You have no power to do such a thing.

Mr. BROWN: We have power to make regulations.

The PRESIDENT: The Act says that a person is entitled to be registered on producing his diploma or diplomas to the registrar of the Branch Council for England, Scotland, or Ireland. If he goes to a Branch Council the registrar of that Branch Council must register him.

Mr. BROWN: Surely that does not demolish the necessity for making regulations as to registration. Let sufficient time be given for the registrars to communicate in order to verify the documents.

The PRESIDENT: The Act does not allow for that and you must proceed by the Act.

Dr. MCVAIL said he was clearly of opinion that the applicant should make the application in his own handwriting.

Mr. HORSLEY thought the Council had a perfect right to make regulations so long as they were reasonable.

The PRESIDENT said there was another point. He understood that various of the examining bodies were in the habit of sending to the registrar lists which contain the names and addresses of the persons who had passed a given examination and he should like to know what the procedure was with regard to these lists.

The REGISTRAR (Mr. ALLEN) said that these lists were without the handwriting of the candidates who had passed. Yet it was competent for the Registrar to register these names without any other application in relation thereto. He did not, however, remember a single case in which a man had been registered in this way.

Sir JOHN BATTY TUKE submitted that the recommendation of the committee was contrary to the Act of Parliament and referred the Council to Section 15 of the Act.

The PRESIDENT read this section, which bore out what Mr. Allen had said.

Mr. HORSLEY pointed out that it was purely permissive.

The PRESIDENT said that there seemed to him to be a doubt whether it would be lawful for the registrar to interpose this new condition as to the handwriting and suggested that the Council or the committee should take the opinion of the legal advisers.

Mr. HORSLEY said that if there was any difference of opinion as to the interpretation of the Act it would be well to have expert advice.

As the outcome of some further discussion it was decided to refer the report back to the committee for further consideration with power to take legal opinion with regard to the legal questions raised in their report and its recommendations.

The Council then resumed and adopted the decisions of the committee of the whole Council. The whole subject therefore remains in abeyance.

Foreign Practitioners in Italy.

The Council proceeded to the consideration of communications, &c., from the Privy Council in regard to the practice of medicine in Italy by foreigners and the application of Part II. of the Medical Act of 1886 to Italy. The communications and documents read were as follows:—

Privy Council Office, London, S.W.,
April 6th, 1900.

SIR,—Referring to the letter from this office of the 29th instant I am directed by the Lord President of the Council to transmit to you, to be laid before the General Medical Council, the accompanying copy of a translation of the Draft Law, referred to in that letter, respecting the position of foreign doctors in Italy.

I am, Sir, your obedient servant,
J. H. HARRISON.

The Registrar of the General Medical Council.

[*Copy. Translation.*]

DRAFT LAW.

SOLE ARTICLE.

For the last paragraph of Article 23 of the Law on Public Health of December 22, 1888, No. 5849, is substituted the following:—

"From the present prohibition are excluded foreign doctors and surgeons expressly called in for special cases, and in the exclusive service of a particular person or family, and those who, holding the diploma of some university or school of medicine abroad, practise their profession among foreigners only; in all cases, however, with the reserve that these latter belong to States which concede the same (*equale*) treatment to Italian doctors and surgeons."

Privy Council Office, London, S.W.,
April 25th, 1900.

SIR,—I am directed by the Lord President of the Council to transmit to you the accompanying copy of a despatch from Her Majesty's Ambassador at Rome, and of its enclosure, on the subject of medical reciprocity with Italy; and I am to request that in laying these documents before the General Medical Council you will inform that body that Her Majesty's Government will, at the proper time, recommend Her Majesty to apply Part II. of the Medical Act to Italy.

A copy of the draft of a proposed order for that purpose is enclosed herewith.

I am, Sir, your obedient servant,
A. W. FITZROY.

The Registrar of the General Medical Council.

(*a*) DESPATCH FROM HER MAJESTY'S AMBASSADOR AT ROME.

Rome, April 14th, 1900.

MY LORD,—On the receipt of your lordship's despatch No. 26, of the 6th instant, I communicated with the deputation which has been charged by the English medical men resident in Italy to look after their interests; and I have now the honour to enclose a copy of a letter which they have addressed to me, declaring that they consider that the privileges enjoyed by them in Italy are just and reasonable, and would therefore justify the application to Italy of Part II. of the British Medical Act of 1886, so soon as these privileges have been confirmed by the Italian law now under consideration on the basis of reciprocity.

I have to request your lordship to communicate this letter to the President of the Privy Council and to ascertain whether he would be prepared, when the occasion arises, to act upon the recommendation thus made and admit Italian doctors in Great Britain to reciprocity. If this were done the position of British medical men in this country would be secure so far as the new Italian law is concerned.

I have, &c.,
(Signed) CURRIE.

The Marquess of Salisbury, K.G., &c., &c., &c.

(*b*) STATEMENT BY A DEPUTATION OF MEDICAL PRACTITIONERS AT ROME TO HER MAJESTY'S AMBASSADOR.

Rome, April 12th, 1900.

MY LORD,—When we, as a deputation representing the English medical men practising in Italy, waited upon your excellency yesterday, you communicated to us that, in the opinion of the President of the Privy Council, the moment appears favourable for the application of Part II. of the Medical Act to Italy.

As this can only be done "if, in the opinion of Her Majesty, Italy affords the registered practitioners of the United Kingdom such privileges of practising in the said country as to Her Majesty may seem just," the deputation beg to draw prominent attention to the fact that they are unanimous in affirming that, not only in their own interests and in those of the other English medical men at the present time in practice in Italy, but also in the interests of their fellow-countrymen who may in future years elect to practise in Italy, they consider that just and reasonable privileges are afforded to them by Italy under the Italian law that allows them to practise amongst foreigners.

The deputation would further add that they have no desire to practise among Italian subjects, and that they would consider it a great hardship, not only to themselves and to those whose interests they represent, but also to those Englishmen who may at any future time desire to practise in Italy, should the English Government refuse to grant reciprocity under the only terms that the Italian law can render it acceptable to the Italians.

In granting the full measure of medical reciprocity to the Italians we suppose that it would be fully understood that the reciprocity granted should only continue in force as long as the Italian law granting us our present privileges was not revoked.

The deputation would respectfully urge on your excellency that though they beg that immediate action should be taken with regard to the granting of reciprocity of medical practice to Italy, it would be advisable to delay the publication of the measure until the draft Bill now before the Italian Parliament has passed into law.

We remain, &c.,
(Signed) T. EDMONSTON CHARLES.
JOHN J. EYRE.
G. SANDISON BROCK.

His Excellency Lord Currie, &c., &c., &c.

(*c*) DRAFT OF A PROPOSED ORDER IN COUNCIL.

At the Court at
The day of
Present:

The Queen's Most Excellent Majesty.

Whereas by the Medical Act, 1886, it is provided (amongst other things) that Her Majesty may from time to time by Order in Council declare that the second Part of the said Act shall be deemed, on and after a day to be named in such order, to apply to any foreign country which, in Her Majesty's opinion, affords to the medical practitioners of the United Kingdom such privileges of practising in the said foreign country as to Her Majesty may seem just, and from and after the day named in such Order in Council such foreign country shall be deemed to be a foreign country to which the said Act applies within the meaning of the second part thereof, and that until such order in Council has been made in respect of any foreign country the said second part of the said Act shall not be deemed to apply to any such country.

And whereas the Kingdom of Italy affords, in Her Majesty's opinion, to the registered medical practitioners of the United Kingdom such privileges of practising in Italy as to Her Majesty seems just.

Now, therefore, Her Majesty doth hereby, by and with the advice of Her Privy Council, order, direct, and declare that, on and after the day of , in the year of our Lord one thousand nine hundred, the Second Part of the Medical Act, 1886, shall be deemed to apply to Italy.

The PRESIDENT said that in the remarks he made at the opening of the session he called attention to the question of reciprocity of medical practice between Italy and the United Kingdom and he practically gave an epitome of what had just been read. The Council now had all the facts before them and it rested with the members to say whether they wished to express an opinion. It seemed to him that the question of issuing an Order in Council lay entirely with the Privy Council, and according to the terms of the Act the Council had really nothing to do with the matter.

What they had to do with was what would arise at a future stage supposing an Order in Council were issued. It would then have to be determined whether the degrees to be registered furnished a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery, and whether the applicants were of good character and were by law entitled to practise in the foreign country whose degrees they possess.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, the communications and documents were entered on the minutes.

Mr. HORSLEY said that the Privy Council were proposing to give away all the privileges of practice in this kingdom to Italians, while Italians were only offering to British practitioners the privilege of practising among foreigners in Italy. That seemed so inequitable that it should not be passed over without some representation to the Privy Council. The General Medical Council had been advised last year that it was perfectly impossible to restrict the practice of anybody registered under Part II. of the Act of 1886; in other words, any person coming to this country would be entitled to practise among all classes of the community, whereas our countrymen in Italy would not be allowed to practise except amongst foreigners. The General Medical Council had never voted in favour of the application of the part of the Act in question, and the Council should approach the Lord President of the Privy Council and point out to him the inequity of the proposition. He wished to move to that effect.

The PRESIDENT asked Mr. Horsley to put his motion in writing.

Dr. MCVAIL said that while Mr. Horsley was doing so he would like to ask whether the Privy Council expected the General Medical Council to make any representation or observation on this subject, because in the letter of April 27th there was not a single word which indicated that the Privy Council asked the advice of the General Medical Council on the matter.

The PRESIDENT: That is so.

Dr. MCVAIL thought that then they should not offer any. The documents sent to them were put before them simply as an intimation and warning that when Part II. of the Act of 1886 was put in operation the General Medical Council would have to help in determining the value of Italian qualifications. It did not seem to him at all advisable for the General Medical Council to interfere.

The PRESIDENT: I have no information that the Privy Council has any mind that we should take any action at this stage.

Dr. MCVAIL: Quite so.

Mr. HORSLEY submitted the following as the motion he proposed:—

That it be respectfully represented to the Privy Council that the application of Part II. of the Medical Act, 1886, to Italy at present would not provide a basis of equal reciprocity of practice between the United Kingdom and Italy as suggested in the despatch of Her Majesty's Ambassador at Rome of April 14th, 1900.

Sir JOHN BATTY TUKE seconded this motion. He considered the matter the most important and serious question in connexion with medical registration that had ever come before the Council. It was not for to-day or to-morrow but for all time. No such action as that proposed on the part of the Government could ever be rescinded, and the possible consequence was that they would have a large number of foreign practitioners coming into Great Britain and Ireland over whom they had no possible control. He did not agree with his colleague who cried out "No, no." He claimed as much right to anticipate as that member did, and he supported his contention on this ground—Italy was a poor country, England was a rich one; as soon as the Italian knew that he could come to this country and have the full privilege of practising here they might look for a large influx of Italian practitioners over whom the Council had no control. He did not see that they should run the risk of having a gross injustice done to the profession all through the country and of having a serious complication of all their arrangements brought about simply because of the 35 or 40 British practitioners in Italy in whose interest the proposition was made, particularly as he understood that it was quite easy for a British practitioner in Italy to obtain from licensing bodies in Italy the qualification that would enable him to practise freely in that country. He hoped with Mr. Horsley that if the Act were applied its application would not be made retrospective.

Mr. TOMES said that the matter had become active in Italy only since a deputation from an association formed in Italy somewhat on the lines of the British Medical Association had converted to their views the Minister of Public Instruction, Professor Baccelli. But within the last month the Italian Chamber had been dissolved and it was possible that there might be a new Ministry. Nobody, of course, knew what that Ministry would do, if appointed, but the thing was stopped for the time being and very likely it would never come on again. He did not think the Privy Council would listen to anything from the General Medical Council on the matter of reciprocity.

Mr. BROWN did not see how it would be out of order to state their opinion to the Privy Council. He hoped the General Medical Council would agree to represent that they should give to foreigners only what they gave to them. He protested against the introduction of anything that would result in the influx of a large number of foreign practitioners into this country and he was sorry that Dr. McVail had somewhat changed his opinion on this occasion. They all knew how vigorous he was not long ago in protesting that such a measure as the Privy Council now contemplated taking would open up the medical practice of this country, not only to Italians, but to practitioners from all parts of the continent of Europe and of America also.

Dr. PETTIGREW, in supporting the motion, said that he quite felt the force of what Sir John Batty Tuke had said, that they should not upset the arrangements of this country for the sake of a small number of their brethren practising in a foreign land, but if they could arrange for mutual privileges he thought that would be a very good thing.

Dr. MCVAIL hoped it would be remembered that at former meetings they had had communications from the Privy Council which amounted to asking the opinion of the General Medical Council on the question of reciprocity and they had sent certain replies. The Privy Council did not need to ask their advice, for Section 17 of the Act of 1886 provided for the passing of an Order in Council. Now that the Privy Council announced a decision were they to go over the whole ground again and endeavour in some way to fight the Privy Council? If the General Medical Council thought that the Privy Council were taking a step that they should not take the only thing they could do was to petition Parliament. He entirely assented to the words of the motion, but he thought that the Council should not take any steps in the matter at all.

Dr. MACALISTER agreed very strongly with Dr. McVail that they should not go again to the Privy Council in regard to this matter. If they did go he believed that they would only get a snub, which they would rather deserve than otherwise. The motion would do no good and might do not only the Council but the cause great harm.

Mr. TEALE said he did feel that instead of strengthening the Council's position by making any representation they would weaken their position for making representation at some future time.

Sir CHRISTOPHER NIXON thought that this was a case in which the Council might have to appeal to Parliament in protection of the rights which Parliament had conferred upon it in the matter of the education of practitioners in this country.

Dr. GLOVER agreed with Sir John Batty Tuke that this question was one of the most important that had ever come before the Council. He did not rise to offer opposition to the motion—he was going to support it, but he was also going to propose an addition to it. The last course which had been recommended to the Council was that they should appeal to Parliament against the Privy Council. He had a very high opinion about the General Medical Council—the most interesting body in the profession—but when they asked him to be a party to set up the General Medical Council against the Privy Council and appeal to Parliament he hesitated to adopt such an audacious line of attack. But had they come to the point when that was necessary? Were they to assume that the Privy Council were not as anxious as the General Medical Council to secure reciprocity of practice He did not think so. He thought that the Privy Council were on the side of the General Medical Council and the side of the profession and he proposed to add to the motion these words:—

The Council would urge upon Her Majesty's Government to use their influence with the Italian Government in promoting legislation on this subject to make reciprocity complete in Italian law as well as English law.

Were they to sit still and let the legislation in contemplation be completed? If this legislation passed they would never have another opportunity to speak on the subject. This was the time when the principle of their procedure ought to be stated, the time for them to make any suggestion which they might have to make on the subject, and he thought that they would be perfectly within their rights and would also commend themselves to all reasonable men if they said that while they acquiesced in the step that was going to be taken let them still see that the proposed legislation was complete. That, he thought, would be perfectly reasonable, and if they voted as they felt he did not think that they would get a snub from the Privy Council if they said that they did.

After some remarks by Sir WILLIAM GAIRDNER,

Sir DYCE DUCKWORTH thought that it was not only British practitioners who were involved, but thousands of their fellow countrymen and country-women who resorted to Italy and would not consult Italian practitioners but wanted to be attended by English medical men. He thought that the Council should take care to see that as far as possible they should be able to obtain such attendance.

The PRESIDENT called upon Mr. Horsley to reply on the debate.

Dr. MCVAIL said he wished to make a proposal before this subject was concluded. He moved as an amendment:—

That as the Privy Council has not asked for the opinion of the Medical Council on the draft of the proposed Order in Council the Medical Council do not deem it expedient to offer any opinion.

Dr. HERON WATSON seconded.

Mr. HORSLEY asked the Council not to accept this amendment. He contended that this was the first time that the General Medical Council had had the opportunity to make up their mind on the great subject now before them. Was it quite certain that the Privy Council did not want to hear anything from the General Medical Council? He maintained that their letter was more than an intimation: it was also an invitation to the General Medical Council to consider their communications and, of course, express an opinion on them.

Dr. MACALISTER intended to support the amendment. He thought it suggested the wiser course.

Dr. LITTLE urged that if the General Medical Council did not take action now they would not be heard at all.

Sir JOHN BATTY TUKE regretted that Dr. McVail had put his amendment forward, for it was playing into the hands of the section of the Council who desired to carry this scheme through in spite of all and every consideration of policy and justice. If the amendment were carried their mouths would be shut and great injury would be done to the profession. He had listened to hear reasons in favour of the amendment; he had heard none. Nothing had been put forward except this, that it was in the interest of some hundreds of people in Italy. The wants of these could be easily supplied if the 35 British practitioners in that country would go and take the last qualifying examination in some Italian university. That was a certain, easy scheme, much easier than the upsetting of the whole arrangements of this country.

The Council divided. They rejected the amendment by 15 votes to 7, five members declining to vote and three being absent. The motion was then carried by 15 votes to 10, two members declining to vote.

Dr. GLOVER'S proposed addition was then put in the following form:—

That the Council would urge Her Majesty's Government to use its influence with the Italian Government in promoting legislation on this subject so as to secure for British practitioners full privileges of practice in Italy such as would be conceded by the law of this country to Italian practitioners.

Having rejected this proposal by 14 votes to 6 the Council adjourned.

TUESDAY, MAY 29TH.

The Council resumed to-day, Sir WILLIAM TURNER presiding.

Proceedings in Camerâ.

The PRESIDENT said that he had an important communication to make to the Council, but it was necessary that it should be made in private and consequently he moved that the Council go into *camerâ* for this purpose.

The Council sat *in camerâ* for two hours.

Financial Aid to the Irish Branch Council.

The PRESIDENT, when the public were admitted, announced that the following resolution had been come to by the Council, viz.:—

That having regard to the duties performed by the Irish Branch Council and to the funds at its disposal it is necessary for the purpose of the due execution of the Medical Acts that the General Council should, as part of its expenses, contribute to the income of the Irish Branch Council the sum of £500 in aid of the expenses of the Branch Council for the year 1900.

The Length of the Session.

Mr. TEALE asked the President what likelihood there was of the work of the session being brought to a termination within a reasonable time.

The PRESIDENT said he wished he were in a position to give a definite answer to this question. He had hoped that they might finish to-morrow, but he quite recognised that the important communication which he had had to make to the Council to-day—which was quite unexpected and was not contemplated in the framing of the Council's programme of business—had rightly taken up a considerable part of to-day's time. He hoped, however, that the Council would make up its mind to finish on Thursday.

The Memorandum on Reciprocity.

Mr. BRYANT, seconded by Sir DYCE DUCKWORTH, moved:

That the memorandum upon reciprocity of medical practice in relation with foreign countries as revised by the Executive Committee be received and entered as an appendix to the minutes and be approved for issue as one of the Council's publications.

The memorandum contains a statement prepared on August 10th, 1899, by Mr. Muir Mackenzie on the instructions of the Council and adopted by the Council on Dec. 2nd, 1899, as expressing the present state of the law of this country in regard to reciprocity of medical practice.

Mr. TOMES suggested that certain corrections with regard to Italy should be made in the memorandum before it was finally approved. In some respects the statement of circumstances was not quite up to date, and while nothing could be described as absolutely incorrect there were passages calculated to convey a wrong impression.

The PRESIDENT said that if Mr. Tomes had any corrections to suggest he might lay them before the Executive Committee and they would be attended to, and other members might, perhaps, adopt the same course and thus simplify matters.

Mr. HORSLEY said there was a fundamental correction which he thought was necessary. This was in effect a legal document and he thought the Executive Committee had made a mistake in having it translated into a foreign language. He was strongly of opinion that the memorandum should be issued without the French translation and he moved as an amendment that it be omitted.

Dr. MCVAIL, in seconding this amendment, said it was impossible for anyone to be quite certain that he had translated accurately a legal document of this character.

Dr. MACALISTER said that the suggestion that there should be a French translation was approved by the Council as a body. As the object of the memorandum was to provide in convenient form an answer to the inquiries frequently received from foreign countries as to the state of our law he thought it most desirable that it should be translated into the language of diplomacy. He might explain that the translation had been revised by a French notary as well as by Mr. Muir Mackenzie.

Mr. HORSLEY said that the Executive Committee had not been instructed by the Council to have a translation prepared.

The PRESIDENT said that the impression made upon his mind by the conversation which took place on this question in December was that the feeling of the Council was that the statement should be translated and he was responsible for moving in the matter in the Executive Committee.

Dr. PAYNE thought that the translation should be retained as likely to contribute to the usefulness of the statement.

The amendment received the support of only two members, Mr. Horsley and Dr. McVail, and the motion of Mr. Bryant being put to the Council was carried.

The PRESIDENT said he thought that it ought to be stated that the revision of the memorandum as to the law in foreign countries had been carried out after communication with the Foreign Office.

The Dental Board of Victoria.

Mr. BRYANT brought up a report from the Dental Education and Examination Committee on an application from the Dental Board of Victoria. The application was for the

recognition of the diploma of the board as entitling its holder to registration in this country, and the committee, after explaining the regulations for the examinations, said they could not advise the Council to accede to the application.

On the motion of Mr. BRYANT, seconded by Mr. TOMES, it was agreed :—

That the Council is unable to recognise the diploma of the Dental Board of Victoria as entitling its holder to registration in the Dentists Register of this country.

The Royal College of Dental Surgeons, Ontario.

Mr. BRYANT brought up the following report on an application from the Royal College of Dental Surgeons, Ontario, viz. :—

The proposition of the Royal College of Dental Surgeons, Ontario—contained in a letter referred to the committee by the Executive Committee on Feb. 26th, 1900—is that a measure of reciprocity in the matter of dental degrees should be instituted between that province and Great Britain. In their opinion it would be more desirable that the respective authorities should establish facilities for admission of persons holding the degrees of the one to the examinations held by the other, than that privileges of registration without examination should be accorded. They further suggest that they make application to the General Medical Council rather than to the several British licensing bodies, because they suppose that it may be necessary that the Council should authorise the bodies to grant this recognition.

Although the matter is one which, perhaps, falls within the discretion of the licensing bodies, such expression of opinion from the General Medical Council may be of use as tending to uniformity in their action. The scheme proposed is that on either side the preliminary examination, apprenticeship and curriculum of the other, be accepted, but that prior to admission to examination an attendance during the last year be required in the country in which the candidate seeks examination.

This does not apply to students, but only to those who have already obtained their qualification in their own country. It therefore becomes desirable to examine into the nature of the curriculum and, so far as possible, of the examinations of the Ontario College.

So far as the special dental side of their curriculum is concerned it appears to be sufficient and to be, roughly speaking, the equivalent of our own. Unfortunately, as much cannot be said of the general side, in which there are some weak points.

Minute anatomy of the head and neck is to be taught at the Royal College of Dental Surgeons instead of at a recognised medical school, and nothing is explicitly said about dissections.

Similarly the lectures on physiology, on medicine, and on surgery are to be delivered at the Dental College, so that the student need never go near a medical school or general hospital, and clinical work would amount to next to nothing—at most the seeing of a few selected cases brought for the purpose.

Had the request submitted been for registration this would have sufficed to ensure its refusal, but as practically an extra year of study in this country is proposed the real question is whether this year will sufficiently supplement the weak points in their curriculum. The principle which has heretofore been adopted in the case of foreign graduates applying for admission to examination by at least one of our licensing bodies has been that the curriculum gone through shall all be accepted if of a *bonâ-fide* character, but that any parts in which it falls short of our own shall be made up by attendance on the subjects in question here; the proposition submitted differs from this existing practice in that attendance upon the courses required of a second year's British student should be accepted in lieu of a detailed filling up of deficient attendance. It appears hardly to constitute a full equivalent; at the same time, it is only examination which is sought, and no one will be found to adopt it by way of getting an easier and shorter curriculum, as it involves attendance upon courses for an additional year after qualification elsewhere. The curriculum of the Ontario College only takes three and a half years as against our four, but the additional year attended here would bring up the total to four and a half.

This being the case it becomes a question whether, whilst one year is required of the Canadian graduate for admission to examination here, bringing his total curriculum up to four and a half years, a somewhat shorter period—namely, a half year—should suffice in the case of a British graduate applying for examination in Ontario, which would bring his total also up to four and a half years.

So far as it is possible to judge, the preliminary examination required in Ontario appears to be sufficient and the questions set in the professional examinations are of an appropriate nature and are sufficiently searching. Some subjects, indeed, are made the subjects of special examination which are not so treated here by all of our boards—e.g., materia medica and jurisprudence as applied to dental cases.

Upon the whole the diploma of Ontario appears to be of a high character, and should the several British licensing bodies, with whom the decision must rest, take a favourable view of the application, and consider that the requirement of general equivalence to their own curricula is adequately secured by the means proposed, your committee think that the General Medical Council need offer no objection.

The subjects of the several professional examinations being somewhat differently distributed in the two countries it would be a question with the licensing bodies whether the final examination here should alone be required.

Your committee recognises the desirability of acceding if possible to a reasonable proposition from one of our colonies.

On the motion of Mr. BRYANT, seconded by Mr. TOMES, the Council resolved to forward a copy of the report of the committee to the dental licensing bodies for their information.

Dentists Act for Western Australia.

Mr. BRYANT reported that the committee had received from the Executive Committee a copy of the Dentists Amendment Act, No. 23, of Western Australia, transmitted by the Secretary of State for the Colonies. The committee were pleased to say that the Act seemed to be quite satisfactory.

The Case of Mr. E. L. Oldfield.

The Council dealt with an application from Mr. Edwin Lenthall Oldfield for registration as a colonial dentist under Sections 8 and 10 of the Dentists Act of 1878. Applicant's letter stated that he was of British parentage and was born in Hobart Town, Tasmania. Since October, 1879, when his apprenticeship with a dental practitioner in the city of Melbourne, Victoria, Australia, terminated, he had continuously practised as a dentist in or near Melbourne, and at the date of his application, April 10th, 1900, was still in practice. When the Victorian Dentists Act, 1887, came into operation he was duly registered as a dentist and received a certificate which entitled him to practise as a dental practitioner in the colony of Victoria. With a view to improving dental education in the colony he founded the Dental College and Oral Hospital of Victoria in 1895. This hospital was for the destitute and was as far as possible carried on in the same educational system as the Dental Hospital of London, Leicester-square. This was the first institution of its kind in the colony and it had been incorporated by the Victorian Government under the Charities Act, 1890. He had been for three years a member of, and an examiner on, the Dental Board and students who had passed the examination held by the board had been admitted by the General Medical Council to the Dentists Register. He had been for three years honorary dentist to the Melbourne Hospital, which was attended by the medical students at Melbourne University. As a practising dentist he had always endeavoured to carry on his business in a professional manner and he had never advertised. His reasons for desiring to be registered were that he should be able to proceed to the L.D.S. Ireland *sine curriculo*, which it was his intention to do. Students articled to him would (other requirements being fulfilled) then have the advantage of such articles on proceeding to England to complete their dental education. He did not desire to be registered for the purposes of practice but for the sake of the advantage that such registration would give him in his endeavours to improve dental education in the colony, upon which work he had been engaged since and prior to the Colonial Act of 1887.

Mr. TOMES said that Mr. Oldfield's application had been made before the Dental Education and Examination Committee came to the conclusion not to recognise the diplomas of the Dental Board of Victoria. But Mr. Oldfield came before the Council as a gentleman who had deserved very well of his profession. Mr. Oldfield had done a very great deal for the advancement of dental surgery in the colony in which he lived, and the falling off in the standard of the education given under the Victorian Dental Board which had recently taken place was not due to him. It had taken place since he left on a visit to this country, and when he (Mr. Tomes) saw Mr. Oldfield lately he had promised that he would use his best efforts to bring the Victorian dental curriculum up to the British standard. Mr. Oldfield was a man to whom one would extend consideration—nay, special consideration.

Mr. TOMES was proceeding to refer to some documents and matters that the Council had considered *in camerâ* and it was deemed advisable that the further proceedings in the case should be in private. Strangers accordingly withdrew. Three-quarters of an hour later, on their re-admission,

The PRESIDENT said: I have to intimate that the Registrar has been instructed to enter the name of Mr. Edwin Lenthall Oldfield in the Colonial List of the Dentists Register.

Medical Aid Associations.

The next business was the reception of a report from the Medical Aid Associations Committee respecting references made to it by the Executive Committee on Nov. 27th, 1899, as to communications in regard to medical contracts received by the Executive Committee on Feb. 26th, 1900, and directed to be transmitted to the General Council.

Dr. GLOVER read the report, which was as follows :—

The Medical Aids Committee met on Tuesday, Dec. 5th, and considered several communications referred to them by the Executive Committee at its meeting on Nov. 27th on the subject of medical contracts in which the question of canvassing arises. These communications were, respectively, from Messrs. Graham and Shepherd, joint secretaries of the County of Durham Medical Union; from L. Cooke, Esq., honorary secretary of the Wigan and District Medical Guild, Wigan; and from the Ashton-under-Lyne Medical Society. The

Medical Aids Committee suggest that these gentlemen should be informed that in any given case where the Medical Council is desired to take action facts and evidence of the implication of the particular registered practitioner complained of will have to be furnished by the complainants (in a statement attested by affidavit).—J. G. GLOVER, Chairman, Dec. 5th, 1899.

On the motion of Dr. GLOVER, seconded by Dr. BRUCE, the report was received, entered on the minutes, and approved.

Dr. GLOVER next read the following as an interim report which the same committee desired to present to the Council:—

On Tuesday, May 22nd, the Medical Aid Associations Committee of the General Medical Council held a conference with four members of a committee of the Council of the British Medical Association on the subject of the formation of a conjoint board for the promotion of a better understanding between the medical profession and the friendly societies. Sir William Turner presided and the following gentlemen represented the committee of the Council of the British Medical Association: Dr. F. M. Pope, Leicester; Mr. C. H. W. Parkinson, Wimborne; Dr. Dawson Williams; and Mr. Andrew Clark.

After a full discussion of the many points of difficulty in establishing a Conciliation Board, the deputation from the British Medical Association Council expressed themselves as having got much light on the subject, and stated that they would report to their Council the result of this meeting. The hope was expressed that at the forthcoming meeting of the Association in August the Association will be able to report its definite conclusions on this important subject to the General Medical Council.

J. G. GLOVER, Chairman.

On the motion of Dr. GLOVER, seconded by Dr. BRUCE, this report was received and entered on the minutes.

The Council adjourned.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the Congregation on May 24th the following were admitted to medical degrees:—

Degree of Doctor of Medicine.—C. P. White, Sidney.

Degree of Bachelor of Medicine.—W. M. Fletcher, H. M. Harwood, W. H. Maxwell, and D. P. Watson, Trinity; N. G. Bennett, St. John's; B. J. Collingwood and J. C. A. Rigby, Caius; and A. Killick, Downing.

Degree of Bachelor of Surgery.—O. F. F. Grünbaum, W. Norbury, and G. R. Slade, Trinity; J. C. Matthews, St. John's; A. E. Bodington, B. J. Collingwood, J. C. A. Rigby, and A. Whitmore, Caius; and A. Killick, Downing.

Mr. F. G. Parsons, F.R.C.S. Eng., has been appointed an additional examiner for the Second M.B. examination this term.

ROYAL COLLEGE OF SURGEONS IN IRELAND: FELLOWSHIP EXAMINATION.—The following candidates having passed the necessary examination have been admitted Fellows of the College:—

Mr. J. H. Conway, Mr. F. C. Crawley, Miss S. Gray, Mr. K. L. G. Gunn, Mr. S. H. Law, Mr. M. J. Madden, Mr. J. F. Mannix, Mr. L. R. More-O'Ferrall, Mr. M. O'Sullivan, and Mr. W. G. T. Posnett.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Wilhelm Zinn, son of the well-known alienist Dr. August Zinn, has been given charge of the Internal Department of the Bethany Hospital.—*Cracow:* Dr. Ignaz Lemberger has been recognised as *privat-docent* of the Pharmacognosis and Microscopy of Food Stuffs.—*Rome:* It having been proposed to establish a clinical professorship of Urinary Diseases, Professor Posner of Berlin has been asked if he would accept it. This, however, he is unwilling to do.

DR. J. L. JONES was at the last meeting of the Melton Mowbray Board of Guardians appointed medical officer and public vaccinator for the parish of Wymondham.

THE NEW INFIRMARY, HIGHGATE-HILL.—The formal opening by the Duke and Duchess of York of this new parochial infirmary, erected at a cost of £200,000, has been fixed for July 16th.

MUNIFICENT GIFT.—Mr. William W. Astor of Cliveden has contributed unconditionally a donation of £10,000 to the Maidenhead Cottage Hospital on his son attaining his majority, and at a meeting of the Hospital Committee on May 25th the institution was declared free to all patients.

APPRECIATION OF MEDICAL SERVICES.—On May 25th the Sanitary Committee of the Hull Corporation awarded a gift of £105 and an increase of salary of £100 per annum to Mr. John W. Mason, M.B., D.P.H. Aberd., the city medical officer of health, for services which he rendered the city during the recent epidemic of small-pox. Gifts at the same time were awarded to every member of the staff employed at the small-pox hospitals varying from one to 50 guineas.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, MAY 24TH.

The Medical Allowance of Volunteer Adjutants.

LIEUTENANT-COLONEL PRYCE-JONES asked the Under Secretary of State for War if he would explain how the medical allowance of 2*d.* each per week to an adjutant of auxiliary forces for himself, wife, and servant was arrived at, seeing that an ordinary medical practitioner would charge about 10*s.* per visit; and, seeing that an allowance of 1*s.* per diem had been found insufficient for providing himself with a servant, and having regard to the fact that the present rate of wages for a groom was about 3*s.* per diem, whether he would consider the advisability of increasing the allowance.—Mr. WYNDHAM replied: These allowances are given in aid of the expenses of medical attendance and of finding civilian servants. The State does not in either case undertake to indemnify the officer for the full expenditure.

Boric Preservatives in Cream.

Mr. LAWRENCE asked the President of the Local Government Board whether he was aware that, while a committee of his department was inquiring as to the use of borax or boric acid as a preservative in cream tradesmen in Liverpool were being frequently prosecuted for its use, and whether until such departmental committee had reported he would use his influence with the local authorities to stop such prosecutions.—Mr. CHAPLIN replied that he was aware that there had been prosecutions of this kind, though his attention had not been drawn to the particular cases referred to by his hon. friend. The Local Government Board had no power to restrain local authorities in the exercise of their powers under the Sale of Food and Drugs Acts, and it did not appear to him that they could intervene in the manner suggested in the question.

Famine and Cholera in India.

Lord GEORGE HAMILTON, replying to a question on this subject, said: There is as yet no material change in the famine situation. Showers have done good in some parts, but the monsoon rains are not yet due. For the past few months a weekly telegram from the Viceroy giving the numbers on relief and the famine outlook has been published in the newspapers. According to this week's telegram the total numbers on relief were 5,607,000. These figures would have been higher but for the cholera which has attacked some of the relief camps in Bombay and in Rajputana, and caused the workers to be dispersed. As yet, however, I have received no detailed reports on this subject. I propose to lay on the table papers showing the spread of the famine during the past six months and the steps taken to relieve distress caused thereby.

Medical Officers in Ireland.

When the House was in Committee of Supply on the vote for the salaries and expenses of the Local Government Board in Ireland, Mr. JOHN DILLON argued that the Board had endeavoured to over-ride the local authorities, and stated by way of illustration that they had issued a ukase to the Ballymena Board of Guardians directing them to allow their medical officers a month's holiday and to pay a substitute, but the Ballymena Board of Guardians appealed against the order, and the Chief Baron decided that it should be quashed, as the Local Government Board had exceeded their powers in the matter.—Mr. GERALD BALFOUR, in reply, said that one of the general rules laid down by the Local Government Board was that each medical officer should be allowed an annual vacation not exceeding four weeks, and that the guardians should pay the medical practitioner temporarily employed such reasonable remuneration for his services as the Local Government Board should approve or direct. He remembered perfectly well stating across the floor of the House last year that the Local Government Board had laid down an order of this kind and that the statement was received from the benches opposite with something like approval. He admitted that the Local Government Board, to the extent of the decision of the courts, made a mistake, but he did not understand that the judges laid it down that the Board had no power to enact a rule or suggested for a moment that such a rule would not be a proper one. Accordingly the matter came down to this, that the Local Government Board did not draft a rule in such a way as to give them the full power they desired to have. The best way to cure any mistake that might have been made would be to alter the rule and no doubt that would be done in due course.

FRIDAY, MAY 25TH.

Carburetted Water-Gas.

Mr. STEADMAN asked the President of the Board of Trade whether there was any legislative regulation or restriction in regard to the use of, and supply by the London gas companies of, carburetted water-gas; whether he was aware that in 1898 a departmental committee appointed by the Board of Trade recommended that the admixture of water-gas with ordinary coal gas should be limited to 12 per cent. and that by a Parliamentary return in the same year it was shown that some of the London companies were even then using considerably over double that proportion; and whether, in view of the fact that there was reason to believe the amount had since been largely increased and that water-gas was four times as poisonous as coal-gas and could not be detected by its odour, he would consider the advisability of taking steps to initiate legislation on the subject, as had long been urged by medical and sanitary authorities and by some means acquaint the public with the fact that they were being supplied with a poisonous article in the name of ordinary gas, so that due care might be taken in its general use.—Mr. RITCHIE replied: The hon. Member must not assume that I admit to the full the accuracy of all the statements contained in the question, some of which might be made the

subject of argument and controversy, but the answer to the first paragraph is in the negative, and with regard to legislation I can merely say that if undertaken it should be general in its character and not confined to London. In any general legislation my right hon. friends the Home Secretary and the President of the Local Government Board would probably have a larger interest than the Board of Trade and I cannot make any promise on the subject at this period of the session.

MONDAY, MAY 28TH.

Proposed Vaccination Return.

Mr. CHANNING asked the President of the Local Government Board whether he had received and considered the resolution of the council of the Association of Poor-law Unions in support of a return of the expenditure of boards of guardians in respect of vaccination in the years immediately preceding and following the commencement of the Vaccination Act, 1898, and whether he would consent to the motion for such a return in the form now on the paper or in some other form.—Mr. CHAPLIN replied: I have caused a communication to be addressed to the Poor-law Unions Association in reply to the resolution referred to. For the reasons stated in the communication it does not appear to me to be expedient that the return should be ordered.

Fatal Accidents in the Railway Service.

Mr. CHANNING asked the President of the Board of Trade whether he could state the total number of coroners' inquests held upon railway servants killed by accidents in which the movement of vehicles used exclusively on railways was concerned in the years 1895 to 1899 inclusive: in what number of such inquests the coroner had applied to the Board of Trade, under Section 8 of the Regulation of Railways Act, 1881, for a representative of the Board to act as assessor; and whether in any other, and if so in how many, such inquests the Board of Trade had been represented by any of its officials to watch or take part in the proceedings.—Mr. RITCHIE replied: Section 8 of the Regulation of Railways Act, 1871, does not apply to Scotland or Ireland. The total number of fatal accidents in which the movement of vehicles used exclusively on railways was concerned that occurred in the five years' period 1895 to 1899 to railway servants and contractors' servants employed on railways in England and Wales was 1869. An inquest was, no doubt, held in each case. In 15 of these cases application was made by the coroner for a representative of the Board of Trade to act as assessor, and in 12 cases such appointment was made. In the remaining case a sub-inspector was directed to attend the inquest and assist the coroner. In four other cases during the period referred to an officer of the Board of Trade has attended the inquest to watch the proceedings.

The Famine in India.

On the motion for the adjournment of the House over the Whitsuntide holidays there was some debate on the famine in India and the steps taken by the Government to relieve distress. Lord GEORGE HAMILTON, in the course of his reply, said that the great difficulty they had to contend with was that not only was the famine more intense in its operation, not only did it cover a larger area than any famine recorded in the present century, but it affected a large number of areas and districts where famine and drought had been unknown. In 1896-97, when they had had no experience for 20 years of famine, he was nervous as to how far the machinery of the Indian Government would respond to the strain then thrown upon it. He was glad to say that on the whole it responded well and the result of the exertions of the Indian Government was that, although there was a considerable loss of life, yet the effects of famine were averted more than in any previous struggle in which the Government had been engaged. The machinery was carefully supervised. A commission was appointed; it went from district to district after the famine was over making suggestions and taking evidence as to how the famine administration code could be improved and strengthened. When the famine broke out he had the satisfaction of having to apply to it machinery which two years before had stood a great stress. But in those districts where famine had never occurred before there had been very great difficulty in getting the people to come rapidly enough into the famine camps. There was a deplorable loss of life—166 died from insanition or from having arrived at the camp so emaciated and in such a deplorable condition that they could not stand the efforts made to revive them. The Government had lent officers to these Native States as well as large sums of money. The advances which had been made to the Native States amounted to 63 lakhs, and this was independent of a very large loan to be made to the State of Haiderabad amounting to two crores. He could assure the House that the Government were watching with the closest attention the progress of the famine. In the course of the next few days the normal rainfall might be expected to begin and then in the next few weeks there would be a steady diminution of those now receiving relief in the famine camps. If it were found at any time that there was any difficulty in supplementing the numbers of officers, medical men, and nurses the Government would not hesitate to draw to the utmost extent on the reserves available in this country; and in the same way, if it were found that there was any lack of financial resources, he should not hesitate to ask the Chancellor of the Exchequer to give the Indian Government the assistance which, as he had already informed the House, he was ready to give.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ANDERTON, W.B., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Resident Assistant Medical Officer for the Crumpsall Workhouse, Township of Manchester, vice A. T. Sissons.

BEGGS, J. E., M.D. Camb., D.P.H., has been appointed Medical Officer for the Grove Hospital, Metropolitan Asylum District.

BENNETT, W. F. COCKAYNE, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., L.S.A. Lond., has been appointed House Surgeon to the Staffordshire General Infirmary, vice F. W. Bonis, resigned.

BROWN, R. B., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health for the Howdenshire Sanitary District.

BROWNE, B. S., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer of Health by the Alcester District Council.

COOPER, W. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of the Abbey Homes, Kendal Union.

CURTIES, W. S., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Ida Hospital, Leeds.

DICKINSON, THOMAS VINCENT, M.D., M.R.C.P., has been appointed Honorary Assistant Physician to the Italian Hospital, Queen-square, London, W.C.

DUNLOP.—J. G., M.B., C.M. Glasg., has been appointed Medical Officer for the Lincoln Workhouse.

EVANS, T. J., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Third Sanitary District of the Llandovery Union.

FAIRFAX, E. W., M.B., Ch.M. Sydney, has been appointed Clinical Assistant to the Chelsea Hospital for Women, Fulham-road, London, S.W.

FORSTER, FREDERICK C., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Resident Medical Officer to the Royal United Hospital, Bath.

FORSTER, R., L.S.A., has been appointed House Physician to the General Infirmary at Leeds.

GORDON, J. J., L.R.C.P., L.R.C.S. Edin., M.R.C.S., has been appointed Medical Officer for the Sidney-road Homes, Hackney Union.

GRIFFITH, A., M.D. Lond., has been re-appointed Medical Officer for Hove and Superintendent of the Sanatorium.

HILDYARD, R. LOXHAM, M.R.C.S., L.S.A., has been re-appointed Medical Officer for the 2A and 2B Districts of the Langport (Somerset) Board of Guardians.

JONES, C. W., M.B., C.M. Edin., has been appointed Medical Officer of Health by the Hale Urban District Council.

JONES, F. S., M.B., B.S. Durh., F.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Prittlewell Sanitary District of the Rochford Union.

LÜCKHOFF, J., M.B. Edin., has been appointed House Physician to the General Infirmary at Leeds.

MACKAY, J. D., M.B., C.M. Edin., has been re-appointed Medical Officer of Health by the Knaresborough District Council.

MAIDLOW, W. H., M.D., B.S., F.R.C.S., has been appointed Medical Officer of Health for the Ilminster (Somerset) Urban District.

MESSITER, A. F., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Epworth Sanitary District of the Thorne Union, vice H. W. Pullan, resigned.

MITCHELL, A. M., M.D. Camb., D.P.H., has been appointed Medical Officer of Health for the Borough of Guildford, vice J. Morton.

MORRISON, W. H., M.B., Ch.B. Vict., has been appointed House Surgeon to the General Infirmary at Leeds.

MORTON, S. ERNEST, M.R.C.S., L.R.C.P., has been appointed Assistant Honorary Medical Officer to the Children's Hospital, Sheffield.

MUNDEN, CHARLES, M.R.C.S., L.S.A., has been re-appointed Medical Officer for the Third (C) District by the Langport (Somerset) Board of Guardians.

MURRAY, ALLEN, has been appointed a Public Analyst under the Food and Drugs Act for Cardigan.

PURSLOW, C. E., M.D., M.R.C.P. Lond., has been appointed Ingleby Examiner in the University of Birmingham.

RODDIS, T. E. E., M.B., C.M. Edin., has been appointed Medical Officer for the Snettisham Sanitary District of the Docking Union, vice J. W. Hopkins, resigned.

SADLER, BERNARD F., L.D.S. R.C.S. Eng., has been appointed Dental Surgeon to the Burton-on-Trent Infirmary.

SHEEN, A. W., M.D. Lond., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Cardiff Infirmary.

SNAPE, LLOYD, has been appointed a Public Analyst under the Food and Drugs Act for Cardigan.

STEWART, A. H., M.B., C.M. Glasg., has been appointed Medical Officer for the Eighth Sanitary District of the North Bierley Union.

TELLING, W. MAXWELL, M.B., B.S. Lond., has been appointed Resident Medical Officer to the General Infirmary at Leeds.

THORNTON, R. G. C., M.B., B.Ch. Irel., has been appointed Medical Officer for the Second Sanitary District of the Wellington (Salop) Union.

Vacancies.

For further Information regarding each vacancy reference should made to the advertisement (see Index).

ANCOATS HOSPITAL, Manchester.—Resident Junior House Surgeon. Salary £50, with board and washing.

BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road, Birkenhead.—House Surgeon for twelve months. Salary £100 per annum, with board, residence, and laundry.

BOOTLE HOSPITAL, Liverpool.—Junior Resident Medical Officer. Salary £80.

BOROUGH HOSPITAL, Birkenhead.—Resident Junior House Surgeon. Salary £75 a year, with certain fees usually obtained.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—House Surgeon. Salary £120 per annum, with rooms and attendance (not board).

CARDIFF INFIRMARY.—Assistant House Physician for six months. Salary at the rate of £50 per annum, with board, washing, and apartments.

CARLISLE DISPENSARY (not Provident).—Resident Surgeon, unmarried. Salary £150 per annum, with apartments (not board). Also House Surgeon. Salary £150 per annum, with apartments (not board). Apply to the Hon. Sec., 23, Lowther-street, Carlisle.

CARMARTHEN UNION.—Medical Officer and Public Vaccinator, to reside at Conwil, for the Conwil (a Welsh) District. Salary £60, with certain extra medical fees. Applications to the Clerk, 7, Hall-street, Carmarthen.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Pathologist. Tenable, subject to annual re-appointment, for not more than three years. Also Clinical Assistant. Tenable for three months on payment of 8 guineas.

CORPORATION OF BIRMINGHAM—CITY HOSPITAL, Lodge-road.—Assistant Medical Officer. Salary £120 per annum, with board, residence, &c.

CORPORATION OF MANCHESTER.—MONSALL FEVER HOSPITAL.—Third Medical Assistant for one year. Salary £100, with board and lodgings. Applications to the Chairman of the Sanitary Committee, Public Health Office, Town Hall, Manchester.

COUNTY ASYLUM, Gloucester.—Locum Tenens for about three months. Salary £3 3s. per week, and all found but liquors.

CRAIGLEITH POORHOUSE AND HOSPITAL, Edinburgh.—Medical Officer, resident. Salary £100 per annum, with board and apartments. Apply to the Clerk, Parish Council Chambers, Castle-terrace, Edinburgh.

CUMBERLAND AND WESTMORLAND ASYLUM, Garlands, Carlisle.—Locum Tenens. Terms 3 guineas per week, with board and residence.

DENBIGHSHIRE INFIRMARY, Denbigh.—House Surgeon for 12 months. Salary £80, with board, residence, and washing.

DEVONSHIRE HOSPITAL, Buxton, Derbyshire.—House Surgeon and Assistant House Surgeon for twelve months. Salary of House Surgeon £100 per annum. Assistant House Surgeon £50, with furnished apartments, board, and washing in both cases.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY, Dumfries.—House Surgeon. Salary £50 per annum, with board and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, London.—House Surgeon for six months, unmarried. Salary £20, with board and residence in the hospital. Also House Physician for six months, unmarried. Salary £20, with board and residence in the hospital.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £85.

LINCOLN COUNTY HOSPITAL, Lincoln.—Assistant House Surgeon for six months. Honorarium for that period £25, with board, residence, and washing.

LIVERPOOL STANLEY HOSPITAL.—Junior House Surgeon. Salary £70, with board, lodging, and washing.

LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY, Loughborough.—Resident House Surgeon. Salary £100 per annum, with furnished rooms, attendance, and board.

MEDICAL MISSION HOSPITAL (SETTLEMENT OF WOMEN WORKERS), Canning Town.—Female Resident Medical Officer. Salary £100, with board and furnished apartments. Apply to the Hon. Secretary, Miss C. Spicer, Montclair, Woodford Green, Essex.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Medical Officer for six months. Salary at the rate of £60 per annum, with board, attendance, and washing.

NEW HOSPITAL FOR WOMEN, 144, Euston-road, London.—Fully qualified Medical Woman as Resident Obstetric Assistant, to take charge of the Maternity Department.

NORFOLK AND NORWICH HOSPITAL, Norwich.—Assistant House Surgeon for six months. Honorarium £20, and board, lodging, and washing.

NORTHAMPTON GENERAL INFIRMARY.—House Surgeon, unmarried. Salary £125 per annum, with furnished apartments, board, attendance, and washing. Also Assistant to the House Surgeon for six months. Board, lodging, and washing provided, and an honorarium of £25 given.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, London.—House Surgeon for six months. Salary at the rate of £80 per annum, with board, residence, and laundry. Also House Physician for six months. Salary at the rate of £80 per annum, with board, residence, and laundry. Apply to the Secretary, City Office, 27, Clement's-lane, Lombard-street, E.C.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £140 per annum, all found except board.

OLDHAM INFIRMARY.—Senior House Surgeon. Salary £85 per annum, with board, washing, and residence.

Births, Marriages, and Deaths.

BIRTHS.

BENNETT.—On May 23rd, at Vancouver-road, Forest-hill, S.E., the wife of Colin E. Bennett, L.R.C.P. Lond., M.R.C.S. Eng., of a daughter.

EDKINS.—On May 27th, the wife of J. S. Edkins, M.B. Camb., of Parkhill-road, Hampstead, and St. Bartholomew's Hospital, of a daughter.

FOULDS.—On May 27th, at Ashlea, Droitwich, the wife of Francis H. Foulds, of a daughter.

HUNTER.—On May 25th, at Duncairn, Helensburgh, the wife of J. Ewing Hunter, M.B., C.M., of a daughter.

LATHAM.—On May 23rd, at Hemingford-road, Barnsbury, the wife of Denyer W. F. Latham, M.R.C.S., L.R.C.P. Lond., of a daughter.

MAC VICKER.—On May 25th, at Street, Somerset, the wife of C. G. MacVicker, B.A., M.B., of a son.

MALDEN.—On May 27th, at St. Lawrence, Tunbridge Wells, the wife of Walter Malden, M.B. Camb., M.R.C.S., of a daughter.

WALKER.—On May 26th, at The Towers, Wakefield, the wife of Frederick Walker, L.R.C.P. Lond., M.R.C.S., of a daughter.

WEEKES.—On May 25th, at Mansion House, Old Brompton, Chatham, the wife of H. Holman Weekes, M.D., M.R.C.S., L.R.C.P. Lond., of a son.

MARRIAGES.

BOND—LAURIE.—On May 12th, at Holy Trinity Church, Worcester Charles Hubert Bond, M.D., D.Sc., the Heath Asylum, Baldwyn's-park, Bexley, to Janet Constance, the only daughter of Fred R. Laurie, of Worcester.

DE MÉRIC—HARRIS.—On May 23rd, at Saint Mary's, Fulham, Henry Eugene de Méric, M.R.C.S., to Edith Huici Harris, eldest daughter of James Harris, of West Kensington.

GOODSON—WATKINS.—On the 16th inst., at the parish church of St. Pancras, London, by the Rev. W. Mirrieless, William Henry Goodson, M.R.C.S. Eng., L.R.C.P. Lond., of Buxton Villas, Leytonstone-road, Stratford, Essex, to Alice Mary, youngest daughter of the late John Watkins, of Halnaker, Chichester, Sussex.

HUNT—STRANACK.—On May 10th, at Saint Paul's Church, Matheran, Bombay, Edward Lewis Hunt, M.R.C.S., L.R.C.P., of Dorset-square, London, to Daisy Beryl May, daughter of F. D. Stranack, of Bombay.

DEATHS.

GIMSON.—At Witham, Essex, on Sunday, May 27th, William Gimson Gimson, M.D., in his 62nd year. Funeral at All Saints' Church, Witham, on Thursday, May 31st, at 3.45 P.M.

GODDE-SMITH.—On May 26th, at Redbourn, Herts, Fredk. Martin Godde-Smith, M.R.C.S., L.R.C.P. Edin., aged 43 years.

HUNT.—On April 4th, at Ferry-road, Christchurch, Canterbury, New Zealand, Frederick Everard Hunt, M.R.C.S., L.R.C.P. Edin., aged 59 years.

LIDIARD.—On May 26th, at Springbank-road, Hither-green, S.E., Sydney Robert Lidiard, M.D., aged 48 years.

SHIRTLIFF.—On May 25th, at Newlands, Ryde, Isle of Wight, Edward Matthew Shirtliff, M.D., aged 63 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE DEGRADATION OF CONSULTATION.

THE following two advertisements occur next to each other in the columns of a Birmingham paper, and the juxtaposition seems to us to warrant our describing the Consultative Medical and Surgical Institution of Birmingham as calculated to bring medical consulting into disrepute:—

POLYPATHIC MEDICAL INSTITUTE, 109, HAGLEY ROAD, EDGBASTON, BIRMINGHAM.

All Chronic Diseases treated on improved and progressive principles. This, together with our perfect system of diagnosis, makes a complete and successful treatment.

INSTITUTES IN ALL CIVILISED COUNTRIES.

Where more capital is invested a larger staff employed, more patients treated, more cures made than by any other known system, and where in the scientific examination and cure of all long-standing diseases and deformities their system has, so far, no equal.

FREE TESTS WITH THE POLYPATHS is offered from May 1st to July 1st, and all who call during these months and book for treatment will receive CONSULTATION, ADVICE, EXAMINATION, and ABSOLUTE TREATMENT OF ALL CURABLE DISEASES FREE OF ALL EXPENSE. Medicine only to be paid for. Hours of Attendance—10 a.m. to 1, 2 p.m. to 4; Evenings, 7 to 9.

The POLYPATHIC COURSE OF LECTURES EVERY THURSDAY, at MASONIC HALL. Afternoons at 3 o'clock (Ladies only); Evenings (Men only), 8 p.m.

To all Lectures in our Educational Work Admission is FREE. All Seats are Free. No collection.

THE CONSULTATIVE MEDICAL AND SURGICAL INSTITUTION, BIRMINGHAM.

OBJECTS.

To LESSEN the STRAIN UPON HOSPITAL CHARITY by PROVIDING, on terms within and under conditions suitable to their pecuniary means and position, MEDICAL and SURGICAL AID to those who would otherwise seek it gratuitously, or be unduly taxed by paying the usual consultation fees.

COMMITTEE.

Arthur Chamberlain, J.P. (Chairman), Messrs. John Bedford, Alderman Cook, J.P., George Cowley, H. A. Garner, George Hookham, J.P., J. S. Nettlefold, J.P., W. T. Smedley, and J. L. Tough.

Consulting Rooms: Cornwall Buildings, Newhall Street.

HOURS OF ATTENDANCE.

10 a.m. to 12 noon, 1 p.m. to 4 p.m., 6 p.m. to 8 p.m. Saturdays: 10 a.m. to 12 noon, and 1 p.m. to 4 p.m. only. Sundays: No attendance.

CONSULTING FEE, Half-a-guinea.

THIS INSTITUTION WILL BE OPEN TO THOSE IN NEED OF MEDICAL ADVICE TO-DAY (MONDAY) THE 21st INSTANT.

When the Birmingham Consultative Medical and Surgical Institution was started it was proposed, if we remember right, to pay two "consultants" £500 per annum and place the rest of their earnings, estimated at £3000 per annum, to the credit of the institute. Such a project for exploiting the earnings of medical men could only be regarded by us with the disfavour with which we regard the action of most medical aid associations. Nor are the medical profession the only persons wronged under the scheme. The public are led to believe that a surgeon or a physician becomes a "consultant" by simply calling himself so. We do not imply for a moment that the medical officer to the institution is other than an entirely capable man and a man of large experience; but the possession of these qualities does not at once constitute him a consulting physician and surgeon, or excuse the institution for selling his services to the public in such a capacity.

A HERBALIST FINED.

OUR readers will remember that in THE LANCET of Jan. 27th we published a letter from a correspondent who had been called in too late to see a patient whom he found dead. The patient had been attended by a man named Purdue, who puts the letters F.C.S.M. after his name. An inquest was held upon the case and the jury returned a verdict of "Death from natural causes." At the beginning of February it came to the knowledge of the medical officer of health of Limehouse that Purdue had been attending sundry cases of diphtheria, Purdue having sent in the usual notification form to that effect. The Limehouse District Board came to the conclusion that something must be done and after some time it was found that the only body which could take any proceedings was the Society of Apothecaries and accordingly the outcome was an action brought in

the Bow County Court on May 23rd, before Judge French and a jury, in which the Society of Apothecaries sought to recover from Mr. Purdue the penalty of £20 which he had incurred by practising and prescribing as a qualified medical man. Mr. Lane appeared as counsel for the plaintiffs and Mr. Young was counsel for the defendant.

Mr. Lane, having explained the legal position of the Society of Apothecaries, went on to say that he did not disguise from the jury the fact that the Society for which he appeared considered the present case a most grave and serious one and one in which it was their bounden duty to take these proceedings. Purdue appeared to practise the calling of a herbalist. He had a shop in Limehouse, but he had no qualification of any kind. In February last a man named Jeffery, the father of seven little children, finding one of them ill and others sickening, went to the shop of the defendant and asked for some ipecacuanha wine. Now, if the defendant had simply supplied that wine nothing more would have been heard of the matter. But the defendant asked Jeffery what was the matter with the child, and Jeffery told him the symptoms as far as he knew, whereupon the defendant said, "I will come round and see it." He went round and examined the child, and finding the throat sore he syringed it, adding, "I have got some medicine at my shop which will do your child good." He subsequently attended the child, declared it to be suffering from diphtheria, and supplied it with medicine, for which he received fees.

Mr. Jeffery deposed to having gone to Purdue's shop. If he had known that the defendant was not qualified he would have gone to a proper medical man when he learnt that his children were suffering from diphtheria. The defendant told him that he would have to report the case to the sanitary authorities.

Mr. Daniel Lewis Thomas, medical officer of health of the Limehouse District, deposed that on Feb. 5th last he received notice from the sanitary clerk of the fact that there were some cases of diphtheria at Jeffery's house. The notice came on the usual notification form. It was usual for these notices to be sent in by medical practitioners when they came across infectious cases. One part of the form contained the query as to whether the case notified occurred in the course of the notifier's private practice, and this was filled up by the defendant with the words, "private practice." He signed himself "J. C. Purdue, Fellow of the Council of Safe Medicine, London." He went to Jeffery's house and found four children suffering from diphtheria. They were all in one room and the mother was also there. Diphtheria took three days to appear fully, and the proper treatment was to administer antitoxin on the first or second day.

John Charles Purdue was then called. He said that he lived at Galt-street, Limehouse, where he had carried on business for three years as a herbalist. He had also prescribed as a herbalist in the City of London. He had been a herbalist for 20 years altogether. On a Saturday night in February, at about 12 o'clock, Jeffery came to him and said that his child was very bad. It seemed to have an obstruction in the throat and he was frightened it would choke. He offered then to go with him and see the child. Nothing was said about medicine at that time. He saw the child and syringed the throat. Next morning, between nine and ten o'clock, Jeffery again came to his shop and said that the child was still very bad, and he went again with him to see the child. He told Jeffery that his child was suffering from diphtheria.

The Judge: But why didn't you tell the people on the Saturday night to call in a doctor?

Witness: Because I knew that nobody could improve on my treatment.

The Judge: Have you passed any examination connected with your practice?

Witness: I had to be examined before I got my diploma from the Council of Safe Medicine.

The Judge: That is, your Herbalists' Institute.

Witness: Yes; it was registered by the Board of Trade in 1893.

The Judge: Registered in the same way as any limited liability company is registered.

Mr. Lane pointed out that the labels on defendant's bottles contained the inscription, "J. C. Purdue, F.C.S.M., London."

The Judge: The defendant admits that he acted as a doctor and that he did not attempt to call in anyone. What else can be said?

Mr. Young said he proposed to address the jury on the question of law. By an Act of Parliament of Henry VIII., 34, 35, a herbalist was entitled to practise so long as he did not infringe the rights of apothecaries by dealing with cases which were not covered by the Act.

The Judge: Is diphtheria covered by the Herbalists Act?

Mr. Young maintained that it was, inasmuch as one of the cases which herbalists were allowed to deal with under the Act was "sores." One of the symptoms of diphtheria was sore-throat and hence that would come under the definition of sores. He submitted that the defendant had not infringed the Apothecaries Act in any way.

The jury discussed together for some time without arriving at a decision.

The Judge reminded them that no personal consideration as to whether or not the defendant had acted wisely or humanely must influence their verdict. The simple question for them to decide was whether the defendant attended as an apothecary.

The jury thereupon returned a unanimous verdict for the plaintiff.

Judgment was thereupon given for the Apothecaries Society, with costs.

This case is eminently satisfactory as far as it goes, but the whole system of unqualified practice in these islands is very far from satisfactory. Granted that unqualified practice or the sale of quack remedies will never be made illegal, we cannot see why vendors of quack remedies or advertising quacks should not be made to pay a far more expensive licence for their trade than the present 1½*d.* stamp. No one may sell tobacco without a licence and the licence does not imply any guarantee as to the genuineness of the article sold. If persons of the Purdue type had to pay £300 a year for a licence or the proprietors of Bodger's Blue Boluses had to pay the same for the right to sell their stuff the deceitful trade would soon be a thing of the past. The present stamp licence on patent medicines is useless, and, despite the notice printed on the label, is still, we fancy, taken to mean that Government guarantees the preparation.

DRUG HABITS.

To the Editors of THE LANCET.

SIRS,—I would like to draw the attention of the profession to what is surely an evil—viz., the treatment of the victims of drug habits in emergency cases. Whenever one of these unfortunates finds himself in an accident ward or a police-station his customary drug is immediately stopped. This is inflicting unnecessary torture and agony. With the chronic alcoholic it is bad enough, but with the opium, morphine, and cocaine *habitué* it is quite a different matter, as the control of the nerve centres is here involved. A person accustomed to take from 10 or more grains of morphia a day is suddenly placed in a position where the drug cannot be obtained. His whole system is tuned in the morphia key, his nerve centres have been for months or years inhibited and his circulatory system stimulated by the poison. To suddenly withdraw this inhibition, &c., is to let nerve storms rampant and to throw the whole working harmony of the organs out of tune, producing intense suffering and agony, as once described to me as "living hell." The victim either becomes insane, collapses, or sinks into extreme neurasthenia. Now, the proper and humane treatment is to give the drug in gradually diminishing doses, and not to totally withdraw it. There is too much prejudice among the profession and the moral is too often enforced at the expense of the victim. In such cases as these drug *habitués*, who are as helpless as babes in the grip of the tyrant, the medical man should think of the suffering and perhaps death that may follow sudden withdrawal.

I am, Sirs, yours faithfully,
ARTHUR A. COTTEW, L.R.C.S. Irel., L.R.C.P. Edin., &c.

Portslade, Sussex, May 27th, 1900.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Can your readers tell me of any home where an officer's wife (who is very badly off) can be surgically treated for uterine disease free of cost? I am, Sirs, yours faithfully,

May 25th, 1900. PAT.

TWO QUERIES.

To the Editors of THE LANCET.

SIRS,—I shall feel obliged if any of your readers can inform me where I may obtain the following:—1. Albert Smith's "Physiology of the London Medical Student." 2. Report of the Royal Commission on the Utility of Experiments on Animals, 1876.

I am, Sirs, yours faithfully,

May, 1900. MIZPAH.

*** 1. Albert Smith's "Physiology of the London Medical Student" was originally published in *Punch* and was afterwards, we fancy, issued as a small book. Our correspondent might apply at *Punch* office or write to a second-hand bookseller. 2. Messrs. Eyre and Spottiswoode could doubtless supply the report if there are any copies left in stock.—ED. L.

THE SEWERAGE OF RYE.

To the Editors of THE LANCET.

SIRS,—On the east side of Rye harbour, Sussex, hundreds of tons of fish are caught every summer and sent to London. The fish are caught in stake nets and are taken out at low water. The longest of these nets goes seawards about a mile. The ground on which these fish are caught is a flat sand and the tide ebbs about a mile. The shore is converted into the famous Rye golf links and is also a favourite place for bathing for children and people who cannot swim. A long stone pier runs out on the east side of the harbour, but it is not high enough and the tide runs over it as well as past it. The set of the ebb stream is to the east, with great force, against and over the wall. The fact that most of the refuse is carried on to the Camber sands is proved by the number of dogs and cats, buoys that have got adrift, &c., that are often strewn along this shore. It is proposed to turn the sewage of Rye harbour into the sea. If so it will mean serious danger to London and other places. Owing to the tons of fish sent away Rye harbour needs a good water-supply. In the tideway on this coast the change of the direction of the stream does not take place at high and low water, as it does in most places, but at half flood and half ebb. The consequence is that no sewage can be carried away. The first three hours of the flood is to the east and the rest to the west, so the sewage would only be washed about, dry on the burning flat sands, and dust, &c., would be blown ashore, and over the fish in the nets. Mr. Moss Flowers, C.E., says the drainage of Rye harbour is a very simple matter. Well, it is easy enough to turn sewage into the water, but not to get rid of it. I believe if Mr. Moss Flowers had stood on the shore three miles west of Rye harbour that he would have formed an opposite opinion. The

land (which is all fishing ground) from Rye to Dungeness stretches out nearly at a right angle to the set of the true tides. It is about 10 or 11 miles from Hastings to Rye harbour, but lots of things out of the Hastings drains are found at sea off this coast. Surely, it is folly to turn sewage right on to a fishing and bathing ground.

I am, Sirs, yours faithfully,

May 29th, 1900. VIATOR.

PS.—The people who understand these things are fishermen, not engineers. Turning sewage into the sea is an abomination on this coast.

"APOMORPHINE AS A HYPNOTIC."

To the Editors of THE LANCET.

SIRS,—Mr. J. Miller in an interesting communication in THE LANCET of May 19th, p. 1481, draws attention to the hypnotic action of apomorphine in certain cases of delirium tremens and is apparently surprised that emesis did not follow the usual hypodermic dose. I would draw his attention to the fact that apomorphine is absolutely inert in alcoholic poisoning (either injected or taken by the mouth). I think this fact cannot be too widely known in view of cases of poisoning complicated with previous injection of alcohol.

I am, Sirs, yours faithfully,

Cheltenham, May 26th, 1900. C. E. ABBOTT, M.R.C.S. Eng.

During the week marked copies of the following newspapers have been received: *Leicester Daily Post, Lancashire Daily Post, Clifton Chronicle, Daily Mail (London), Westminster Gazette, Gainsborough Leader, Sun (London), News of the Week (London), Irish Figaro (Dublin), Bradford Observer, Dundee Advertiser, Nottingham Daily Guardian, Folkestone Herald, Birmingham Daily Post, Macclesfield Courier, Kelso Mail, Hereford Times, Staffordshire Advertiser, Daily Express (London), Sheffield Daily Telegraph, Times of India, Pioneer Mail, Citizen, Scotsman, Builder, Architect, Leeds Mercury, Bristol Mercury, Cape Times, Buchan Observer, Liverpool Daily Post, Brighton Gazette, Yorkshire Post, Aberystwyth Observer, Birmingham Daily Gazette, English Mechanic and World of Science, Sanitary Record, Reading Mercury, City Press, Hertfordshire Mercury, Local Government Chronicle, Mining Journal, Local Government Journal, Surrey Advertiser, London Argus, The Anglo-Celt (Cavan), Madras Times, Walsall Advertiser, Weekly Free Press and Aberdeen Herald, Tunbridge Wells Standard, Nuneaton Observer, Highland News (Inverness).*

FRIDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.).

SATURDAY (9th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (6th).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Paper:—Mr. A. Doran (President): A Case of Extra-uterine Gestation in which Fœtal Death occurred at the Eighth Month after Spurious Labour, Abdominal Section two months later.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY (5th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. W. Ewart: Consultation. (Skin.)

WEDNESDAY (6th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—5 P.M. Mr. W. Rose: Clinical Lecture.

EVELINA HOSPITAL (Southwark-bridge-road, S.E.).—4.30 P.M. Mr. F. C. Abbott: Acute Intestinal Obstruction in Children. (Post-graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Maguire: The Dynamics of the Circulation in Disease.

THURSDAY (7th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—2-3.30 P.M. Mr. H. Pinch: Class. Clinical Microscopy. Demonstration VII. 4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. P. Dunn: External Diseases of the Eye.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. Murray: Medical Cases. (Post-graduate Course.)

FRIDAY (8th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. R. Lake: Consultation. (Ear.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

Two Clinical Lectures
ON
PRIMARY SYPHILITIC CHANCRES.

Delivered at the London Hospital on Feb. 16th and March 2nd, 1900,

BY JONATHAN HUTCHINSON, JUN., F.R.C.S. ENG., &C.,
SURGEON TO THE LONDON HOSPITAL, ETC.

LECTURE II.[1]

Delivered on March 2nd, 1900.

GENTLEMEN,—With regard to the bubo that accompanies primary syphilitic chancres, in the last lecture we noted that out of 125 cases of which I had careful records it was not absent in a single one, and that in only two out of the 125 cases had it the unusual characters of suppuration or of inflammation. The characters of the bubo are really in many cases of greater diagnostic value than are those of the actual sore. It has been said that sometimes the bubo is absent, and some French observers have estimated that in about three per cent. the glands are not appreciably enlarged. Well, you see, there are obvious fallacies. The patient may be stout and his inguinal glands may be very difficult to examine, and I believe that this fact probably accounts for most of these supposed exceptions. The bubo is, at any rate, practically constant and can be found if careful search be made for it. Almost the only case which I could personally adduce in favour of a belief that sometimes the nearest lymphatic glands are not enlarged with the primary syphilitic sore was, briefly, as follows. A man came with a large hard chancre at the furrow of the penis and with tortuous lymphatic cords running up the penis. He was repeatedly examined during the four weeks that ensued after the sore had been noticed, and no enlargement whatever of the inguinal glands could be detected during the whole of this time. He was not at all a stout subject. I regret that the case was then lost sight of, and therefore it is only an incomplete observation. I mention it merely to emphasise the slight evidence in favour of the belief that the bubo is sometimes entirely absent in the case of primary syphilitic chancres. On the other hand, it has been asserted that sometimes there occurs a syphilitic bubo without any primary sore, the so-called "*bubon d'emblée*." That I believe in, though it is excessively rare. And recollect there is a fallacy, with regard to women especially, that the primary sores are very easily overlooked, and although a primary syphilitic chancre, as a rule, will persist (unless diagnosed and properly treated) for weeks and even months, there are some primary syphilitic sores which are quite insignificant and which very soon spontaneously heal leaving no trace behind. As will be readily understood, in women it is often difficult to find the primary sore. One often comes across cases of secondary syphilis in women in whom no history of a sore or evidence of a bubo can be found. Some of these cases are accounted for by the chancre being on the cervix uteri, in which case the bubo will be within the abdomen. The vaginal wall is not a common site for chancres, but the cervix uteri is more often affected and I have seen several examples.

You all know the characters of the typical syphilitic bubo, how the oblique set of inguinal glands—sometimes only the innermost of them, sometimes the more central ones, occasionally the highest glands of the vertical femoral set—are enlarged. Some of the lymphatics of the penis and scrotum can occasionally be dissected out into the upper glands of the vertical femoral set, confirming what has been observed clinically. The bubo is often situated on the opposite side to the primary sore—e.g., the sore being on the right side of the penis the chief bubo may be on the left side owing to the crossing of the lymphatics. As you know, the inguinal glands may be swollen first on one side and then after a time those of the opposite side become also affected. Enlargement of the inguinal glands may develop during the secondary stage as part of the general adenopathy. For instance, you may see a case of chancre of the lip in which the inguinal glands are enlarged, due to general infection through the blood-stream.

A few words as to what may be termed the giant bubo; and the following case may be quoted since it illustrates many points of interest in connexion with syphilis. A young man, aged twenty-two years, florid and healthy-looking, with a good family history (though phthisical tendencies were not excluded from it), contracted a chancre on his lower lip in October, 1894. He went to a medical man, but it was not until January, 1895—that is to say, four full months afterwards—that the syphilitic nature of the sore was recognised and the proper treatment instituted. There were then large buboes of both sides of the neck. He took mercury for only three months, and then irregularly, so that one would say that the treatment was very imperfect. He came to me in November, 1895—that is to say, over a year since the contraction of the syphilis. The site of the chancre was then conspicuous, and he still had a huge bubo on each side of the neck. These buboes were painful and threatened to break down, looking exactly like masses of tuberculous glands. However, in the belief that they were syphilitic I prescribed four grains of grey powder per diem and made him rub in oleate of mercury ointment. After a time both tonsils became ulcerated and had to be cauterised with nitrate of silver, sulphate of copper, &c., but the bubo did not disappear. He was markedly anæmic from the first, and though he had no cough and no signs of mischief in the lungs I could not help thinking that it might be a case of tuberculosis in a syphilitic patient. Iron was prescribed with the mercury, and at length, after nine months of steady treatment, or nearly two years after the infection, the glands wholly subsided without breaking down at all. I must admit that at one time I was inclined to advise him to have them excised, believing that they were in part tuberculous. But they all went down, so one may be certain that it was a case (and a very unusual one) of syphilitic adenopathy. In September, 1896, at the end of two years after infection, and after nine months of steady treatment by mercury, he came again with painful synovitis of the knees. This subsided under iodide of potassium and mercury and cod-liver oil, leaving no trace behind. In March, 1897, at the end of two and a half years after infection, he was florid and healthy again, and there was no trace of enlargement of the glands. He still showed an interesting symptom, that of recurrent induration at the site of the chancre in the lower lip, which soon yielded to treatment.

This case illustrates, first, the danger of overlooking a primary chancre—for it was four months before the right diagnosis was made; secondly, the difficulty in getting the usual rapid therapeutic effects of mercury in such a neglected case; thirdly, the long persistence of huge buboes, their slow but complete yielding to treatment, and the occurrence of relapsing induration at the site of the sore; and, finally, the coincidence in the same subject of symmetrical syphilitic joint-disease and syphilitic disease of the lymphatic glands.

Although syphilitic joint disease and syphilitic gland disease are both rare—I am not thinking of primary buboes, but tertiary syphilitic gland disease—there is a strong tendency for both to occur in the same individual. Now is not this of extreme interest in comparing syphilis with tubercle? In tubercle disease of lymphatic glands and disease of joints are two of the main symptoms, and it is so with syphilis. If you look up the literature you will find many cases recorded in which a patient who has had tertiary syphilitic gland disease subsequently has syphilitic arthritis, or *vice versâ*. The case which I have just narrated raises the question, which is discussed from time to time, Is syphilis which is contracted from congenital chancres more severe than that which is contracted from the ordinary primary chancres on the genitals? The answer is a very simple one. The reason why these cases often seem to be more severe than those following genital chancres is simply that the nature of the sore is overlooked. They are exceptional cases in this, that for perhaps two, four, or six months the nature of such a sore is not diagnosed, the patient, therefore, has no treatment, the virus gets a thorough hold on the system (if I may use the term), and one knows that in these cases of severe primary and secondary syphilis with much delayed treatment you will have more difficulty in overcoming the virus, and the later symptoms will probably be severe.

[1] Lecture I. was published in THE LANCET of June 2nd, 1900, p. 1575.

That leads me to state briefly my belief as regards severe and mild attacks of syphilis. You ask yourself the questions, Is syphilis the same disease in all its victims? Are there mild and are there severe attacks, or does the severity depend wholly on the individual? As to whether the dose of the poison varies we know and can say nothing. I certainly believe in one man having a mild attack of syphilis and another a very severe one, but the influence of treatment is a most important thing and especially the date at which that treatment is begun and the persistence with which it is followed up. At the same time it must be granted that, apart from treatment, some cases are comparatively mild. This may partly account for the strange statement seen in some of the books, especially foreign ones, that case after case of undoubted syphilis was "cured" with a dozen subcutaneous injections of small doses of mercury. It is certain that ordinary cases of syphilis are not, and cannot be, cured by any such treatment. We know this fact also—that where secondary symptoms have been mild, either as a result of treatment or not, there is no guarantee (if mercury be not continued for a long time) that tertiary symptoms will not occur or may not be very severe. Examples of this are seen in those who wilfully conceal their malady or in whom it is not diagnosed. I will mention to you an instance. An elderly married man, with every inducement to conceal his frailty, deliberately deceived a practitioner as to the nature of a secondary syphilitic eruption which was at first of the ordinary erythematous type, and then it became much more complicated, ultimately ending in a very severe attack of syphilitic pemphigus. Although he had the remains of a chancre present for several months he persuaded his medical adviser that his symptoms were due to anything but syphilis, and the consequence was that he never had any specific treatment until he got into such a deplorable state that he very nearly died from syphilitic cachexia. The case would probably have caused no trouble whatever had mercurial treatment been commenced early.

Now, a word or two as to phagedenic chancres. You will probably not see many nowadays, but they may give a great deal of trouble. We will briefly note that the term is very vaguely used. Many primary syphilitic sores are destructive without being really phagedenic, especially when they occur in concealed sites—e.g., at the furrow of the penis—and become complicated by a great number of septic organisms. Any primary syphilitic sore may be phagedenic in a sense, but of the true acute destruction, the real rapid phagedena, one would say that it is not necessarily a sign of syphilis. The following are some of the characters of this true phagedena. The incubation stage—the period between the inoculation and the development of the sore—is very short (generally only a few days), much shorter than is the case with a syphilitic sore which assumes its typical characters in three weeks. The bubo is slight or absent with a phagedenic sore and mercury has little or no effect in checking the destructive process. Finally, many cases of phagedena—I do not say all—escape secondaries. These are briefly the conclusions one has learnt from a study of a good number of cases of phagedena. Although it usually occurs in concealed sores, where there is phimosis, it may attack the more open parts, such as the vaginal orifice. I remember one case in which the greater part of the vulva and labia on both sides were destroyed by a rapid phagedena, not followed by syphilis. I would, of course, impress upon you the significance with concealed sores of hæmorrhagic discharge. A little oozing of blood may mean that the ulcer is rapidly eating into the tissues, and if there be a foul-smelling discharge the two signs indicate that the prepuce should be slit up without delay and the sore thoroughly exposed. It should be thoroughly cleaned under an anæsthetic and either pure carbolic or acid nitrate of mercury should be applied. The patient should then be kept in a bath of very weak solution of bichloride of mercury, the hot water being frequently changed, and he should remain for some days in this bath. The continuous immersion and exposure of the sore to the action of the water should be employed until the sore begins to take on a healthy appearance. The value of continuous bath treatment in phagedenic chancres, although it has been known to the profession for very many years, is forgotten now and then, and at the last meeting of the British Medical Association two cases of fatal phagedena were narrated (in one the patient was a woman), the chief point of which to my mind was that the bath or immersion treatment had not been thought of or tried in either. All sorts of escharotics had been used, but no immersion treatment, yet that is the safest, least painful, and simplest of all the methods. There is of course danger of severe hæmorrhage in phagedenic chancres. I have known troublesome bleeding occur from the dorsal artery of the penis under such circumstances. Then there is the risk when the sore is on the under surface of the penis of ulceration into the urethra and fistula. I have seen several cases where the glans penis had been wholly eaten away, and of course a stricture followed in the urethra. You know that tertiary syphilis does cause phagedena, and in one such case, a rather slow phagedena of the penis where the glans had been reduced to a mere fragment and the penis was entirely mis-shaped and distorted, I was driven to amputate at the man's own express wish, and gave him a decent-looking organ, although it was shorter than usual.

The question of phagedena leads me to mention a peculiar form of primary sore which, though it is not phagedenic, is somewhat alarming in appearance, and that is the primary chancre which resembles a malignant pustule. Its characters are these: there is a great deal of surrounding inflammation and the part is much swollen: in the centre is a sore covered with a thick blackish dry scab looking like a dry eschar. The ugly term "ambustiform" has been recently applied to this form of chancre, suggesting to classical minds the slough produced by the cautery. I believe these chancres are always syphilitic, but they are not common.

Now we come to the important question of the difficulties in the diagnosis of primary infecting sore—difficulties which every surgeon is certain to be confronted with. First, as to the decision between "soft sores" and true infective chancres. The term "soft sore" is so useful that we shall be obliged to retain it. You know that a soft sore may become indurated after the lapse of a certain time. The soft sore is said to be due to a specific bacillus, but it is premature to speak positively as to that. As to the true primary chancre, we are ignorant as to what sort of bacillus causes the infection or whether it is a micro-organism at all, and this in spite of the work of a great number of skilled bacteriologists. As you know, soft non-infecting sores are attended in many cases by abscesses in the groin, and the sores themselves are usually multiple. We saw that the primary infecting sores of the genitals were multiple in only about one in five cases. Out of 125 examples of primary infecting sores these were single in a little over 100. Where you have eight or ten or more pus-secreting sores you can feel little doubt about the diagnosis, especially if the glands are already painful and inflamed. But it must not be forgotten that one of these soft sores may take on induration and prove infective. Note that the longer the time which has elapsed before the sore is noticed the greater the probability is that it is infective. The soft sore chiefly comes on from three to five days after infection; the primary chancre may not show itself for from two to three weeks or even longer. The character of the bubo is often of more importance than the chancre; that point we have already dwelt upon. But I want to urge this point, that those who have had the most experience in the diagnosis become more and more cautious in giving a final opinion until a certain amount of time has elapsed from infection. The patient will say, "Is this sore a primary chancre or not? When can you say positively?" The answer is that in three or four weeks after infection you can generally decide, but that before that time no one can tell with certainty, and that sometimes it may be six weeks or even more before you can say positively. Every one of us will, in all probability, make mistakes in diagnosing between soft sores and primary syphilitic sores. The more experience one has the more cautious one gets in giving a positive diagnosis until a certain time had elapsed. I wish that bacteriological examination were likely to be of assistance, but I doubt if it ever will be. Even granted that the soft chancre has a peculiar bacillus its presence would not prove that the patient had not acquired the syphilitic virus also. We must therefore go mainly on the clinical investigation of the chancre and bubo from all their aspects, not forgetting to examine for indurated lymphatic cords.

It may be said that the mercurial treatment can now be conducted with so little damage to the general health that in any case where you are doubtful as to diagnosis the real benefit of the doubt will come in giving the patient mercury. That is to some extent true, but it is not a very satisfactory position, say, at the end of six months after you have been

giving mercury, to feel still doubtful as to the true nature of the case. The patient may ask you at the end of that time whether he has had syphilis or not, and whether he may marry in a year or two, or whether he is to go on with the treatment for two years. You will at once see that the position then is a difficult one. Still, some authorities hold that when in doubt you should give mercury. The general opinion seems to be veering round towards that, and it is so because nowadays mercury can be given with proper safeguards with so little damage to the patient's health, occupation, or his general habits that it has become a mere bagatelle to go in for nine or eighteen months' mercurial treatment. Still, you should certainly wait a little time before making a diagnosis. I may mention, by the way, that I knew of a case where a gentleman went to a surgeon, a specialist, on the day after contagion—that is to say, within 24 hours. The gentleman said, "I think I have got syphilis." There was nothing abnormal to be seen, not even an abrasion. The surgeon said, "You had better have mercurial injections; anyhow it will prevent your getting tertiary symptoms." So that though there was never the slightest symptom of venereal disease this man went through a course of mercurial injections until he got tired of them. That is perhaps going to extremes and I do not think it should be held up as an example to follow.

There are some interesting cases of tertiary ulceration of the genitals which may readily lead you astray. The patient himself or herself thinks that the ulcer is syphilitic and you are apt to treat such lesions as primary sores. I show you a picture of a primary sore which fairly resembles a gummatous ulcer in its shape and in the slough. I will now give you the notes of a case in which I made the mistake myself. A man had slight secondary syphilis in 1893. He was treated with green iodide of mercury and, as generally happens when green iodide of mercury is given, the treatment was imperfect. In 1895 he suffered from severe ulceration of his cheek and palate. He was given liquor hydrargyri and iodide of potassium for 12 months. In 1896, three years after his secondary symptoms, he came to me with a supposed chancre spreading round the furrow of the prepuce. It was 10 days after suspicious intercourse and it looked uncommonly like a fresh chancre. As he had had syphilis two years before it was hardly likely to be a second infection. I treated it locally with black-wash, calomel, iodoform, and pure carbolic acid applied repeatedly and vigorously. It was only at the end of two months that I recognised that it was merely a tertiary sore and I gave iodide of potassium with the result that it speedily melted away. This example may impress upon you the fact that tertiary sores on the genitals are very apt to give rise to mistakes in diagnosis. I have known of a number of cases of which I will mention only one or two of the most interesting.

A woman came to the out-patient department here with a large inveterate ulcer of the leg which was diagnosed to be epitheliomatous. The leg was amputated through the knee-joint and the microscopical sections, which I saw myself, were not conclusive as to epithelioma; they were more like those of a gummatous ulcer. Six months later she came under my care with a large hard-edged ulcer of the left labium majore and some swelling of the inguinal lymphatic glands. This ulcer was very like a commencing epithelioma. On the other hand, it was fairly like a tertiary ulcer. Having seen these sections of the ulcer of the leg I thought that it was tertiary syphilis. But as it was in a perfectly convenient position for excision and she was an elderly woman, and as therefore there was likelihood that it might be epithelioma, I excised it, and microscopical examination again negatived epithelioma and pointed strongly to tertiary syphilis.

A man who admitted having had gonorrhœa ten years and two years previously came to me on account of a large gummatous ulcer on the under surface of the penis, unaccompanied by any marked enlargement of the lymphatic glands. There had been exposure to contagion within a short time. On examining his body all over I found a large inflamed node on the right clavicle which he had not mentioned, and another softening one over the manubrium sterni, proving the tertiary nature of his complaint, although we could get no history from him of primary syphilis. All the lesions were cured by iodide of potassium.

Cases of extreme interest sometimes occur of what is called relapsing induration at the site of a former chancre. As a matter of fact, my father and Professor Fournier were the first to call attention to these peculiar cases. The main facts about them are the following. At the site of a primary chancre, years after the infection and with or without exposure to fresh risk, induration occurs, which as a rule does not lead to ulceration but persists an indefinite time, sometimes, however, breaking down in the centre. It is hardly ever accompanied, as far as my experience has gone, with marked enlargement of the inguinal glands. It may occur quite apart from any fresh contagion, though it is curious how often you get a history of this. The recurring or relapsing indurations may occur any number of years after the primary disease, and one's belief is that they are of the same nature as gummatous infiltrations. That is the best way of regarding them and it emphasises the fact that as a rule iodide of potassium effects a speedy cure and is the best drug to give. The subject is of great interest with regard to the germ theory of syphilis. We know how closely syphilis imitates tubercle in many of its effects and that residual tuberculous abscesses or relapses of tuberculous affections in the lungs and the joints occur in an individual many years after the disease has quieted down. It is tempting to suggest that these relapsing indurations and gummatous ulcerations at the site of primary sores are due to a sort of re-awakening of the germs of the syphilitic virus which have lain dormant for years close to the scar. But it is pure theory; we cannot dogmatise as to the syphilitic virus; we do not even know that it is a bacillus.

I would impress upon you the importance of not overlooking an epithelioma of the genital surfaces (especially of the penis), thinking it is a primary sore. Most of the cases of epithelioma of the penis which I have operated upon here—and they amount to a considerable number—have been those of patients who have come up to the Lock Hospital believing that they had a venereal sore. In the last case, which was here a week or two ago, the patient had been sent up from the country and had been for six months under treatment with epithelioma of the penis, the treatment having been, however, entirely anti-syphilitic. I need not impress upon you the danger of making that mistake in diagnosis. It does not matter very much, perhaps, if you overlook a primary sore for a few weeks, but it is of the greatest importance that an epithelioma should not be neglected or overlooked. And I would say this: Never prolong unduly the trial of mercury and iodide of potassium in a doubtful case. If the ulcer is a primary chancre it melts away, as a rule, under mercury properly given. If it be epithelioma no effect will be produced in the course of two or three weeks, and that time should be enough to enable one to come to a decision as to the nature of the sore. Epithelioma of the penis may occur either in the form of a cauliflower growth or of a disc of induration, the latter being extremely like a primary sore, and if it be concealed by the prepuce the diagnosis is undoubtedly difficult. In doubtful cases one must slit up the prepuce, and if that be done the difficulty in diagnosis is soon cleared up. It may here be noted that molluscum contagiosum occurs on the genitals not infrequently. I have seen many cases and have a strong belief that they are usually due to inoculation during intercourse. If one of these molluscum nodules is shed spontaneously the ulcer left may possibly be mistaken for a chancre.

The following case is true though it may appear incredible. A man came with a sore on his penis which proved to be due to vaccination. The history was this. He was a married man and his wife was suckling a child who had lately been vaccinated. In some way the vaccination virus had been conveyed from the infant to the genitals of the mother and she had a vaccination sore on her vulva. The man also was susceptible and contracted a vaccination sore on the penis from his wife.

As to the treatment of primary sores I will be very brief. As a rule, whether the sore be hard or soft one should avoid ointments. They rarely suit, and I never use them. Drying powders are far better, and it is interesting to note that in England in the fourteenth century, before they had any experience of true syphilis, soft sores of the penis were directed to be treated with the ashes of burnt linen. They could not have devised a more sensible treatment. Under simple antiseptic treatment soft sores will generally heal rapidly, and undoubtedly for the soft sores and for the doubtful sores iodoform and boric powder—e.g., in the proportion of one to four—can hardly be improved upon. Calomel powder, either diluted or not, and the old-fashioned

black-wash are excellent applications for venereal sores. For soft chancres I believe strongly in cauterisation with pure carbolic acid, with which there is no need to apply cocaine as there is not much pain and it causes the soft sores to heal up rapidly. The treatment is also valuable because in many cases I believe it prevents the occurrence of suppurating bubo. If, and as soon as, your diagnosis is certain that the case is one of primary syphilis, give mercury. There is nothing which will cause the induration to melt away so rapidly as the internal use of mercury. With regard to excision in doubtful cases I could give several instances where excision has proved quite useless, although it has been done within a few days of contagion.

A word, in conclusion, as to the history of the occurrence of primary sores. Be very cautious in accepting patients' statements. They often conceal the fact that they have had primary sores, and, of course, when months or years have elapsed they forget all the characters of them. You will learn to distrust the statements of patients as to the non-occurrence of venereal sores in the dim and distant past. Sometimes you will be told that although the patient had certain sores it was quite impossible that they could have been venereal, because the individual was "above suspicion." If a man ostentatiously parades the statement that he is above suspicion distrust him all the more. You probably know Sir Peter Teazle's opinion of humanity in general; if you do not know it I will not spoil your pleasure in looking it up.

Two Clinical Lectures

ON

THE USE OF MASSAGE IN RECENT FRACTURES AND OTHER COMMON INJURIES.

Delivered at St. George's Hospital on Jan. 30th and Feb. 27th, 1900,

BY WILLIAM H. BENNETT, F.R.C.S. ENG.,

SURGEON TO ST. GEORGE'S HOSPITAL; MEMBER OF THE COURT OF EXAMINERS, ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC.

LECTURE II.[1]

Delivered on Feb. 27th.

GENTLEMEN,—In my previous lecture the expiration of the time at my disposal compelled me to omit any mention of two varieties of fractures of considerable importance from the point of view of the treatment by immediate massage—viz., fracture of the patella and of the olecranon. Until recently, as you know, the classical method of treating these fractures was by long confinement in splints or fixed apparatus (the period in the case of fracture of the patella extending sometimes to as much as a year or even more) with the object of obtaining as firm a union between the fragments as possible. Under such circumstances it cannot be considered remarkable that in many cases the difficulty in obtaining free movement at the knee at the end of the splinting period was extreme and that in some cases, indeed, the pain and distress entailed in the necessary treatment were more than the patients could endure. Those of you who have had no experience of the old treatment will get a good idea of the difficulties connected with obtaining subsequent free movement by reading the account which John Hunter gives of his own case. So great, indeed, was the pain sometimes under these circumstances that a certain number of people who had sustained a fracture of the knee-cap rather than bear the pain entailed in getting free movement preferred to remain with the limb more or less stiff. Speaking generally, the stiffness that follows on a fracture of the patella treated upon the old lines depends largely on the fixation of the upper fragment to the anterior aspect of the femur at the time when attempts at movement are commenced—not, of course, by bony ankylosis, but by adhesions which, forming around the margin of the knee-cap, so tighten the soft parts about it that it is sealed to the surface of the femur. In attempting to get movement in these cases when treated, as I have said, in the olden way, no really good result could be obtained until the adhesions were loosened—a difficult and painful process which was rendered necessary merely because the parts had been confined so long in splints without movement. Moreover, the strain put upon the parts under these circumstances frequently led to a great stretching of the uniting medium. The upper fragment of the patella remained, in fact, at first fixed and before the exercises had resulted in the breaking-down of the adhesions any movement obtained was at the expense of the stretching of the union, the stretching in some cases being very great; but even in such cases so long as the upper fragment ultimately became freely moveable on the femur a fairly good limb resulted in the majority. In the absence of the treatment by suture now so commonly employed the final result is dependent mainly upon two points: (1) the amount of laceration of the lateral expansions about the knee at the time of the injury (the less the lateral expansions are ruptured the more strength is there left in the joint after the fracture); and (2) the amount of mobility finally retained by the upper fragment of the patella. If the fragment does not contract inveterate adhesions and finally becomes freely moveable upon the femur a more or less useful limb follows, the strength of the limb, as a rule, then being in inverse ratio to the length of the uniting medium. If, on the other hand, fixation of this upper fragment occurs, then the interference with the mobility and strength of the joint is so great that the patient is greatly crippled.

The first object, then, in a case of a fracture of the patella, whether wiring has been practised or not, is to prevent by constant manipulation any chance of adhesion of the upper fragment to the femur—a treatment which excludes any form of splint which makes the patella inaccessible. This necessity for securing free mobility of the patella is not confined to cases of fracture, but if a rapid and perfect result is to be obtained it should be used in all cases of inflammation of the knee-joint, traumatic or otherwise, liable to be followed by stiffness. This is a point to which reference will again be made.

As I have already said, this method of treatment makes the use of fixed immoveable apparatus impossible, such, for example, as plaster-of-Paris, silicate of potash, and the like. I may at once state that I have no doubt that the sooner these stiff immoveable appliances become obsolete the better it will be in all cases of damage of joints and in the neighbourhood of joints. The stiffness and pain which so often followed in fracture of the patella when treated upon the old lines were much more frequently due to the treatment than to the injury. The best results which follow fracture of the patella when not subjected to the wiring treatment will be obtained by immediate smooth massage and patellar manipulation, followed in a fortnight or earlier by gentle passive movement of the knee. By such means in the majority of instances a useful limb may be expected in three months, all splints being discarded at the end of the first month. It is remarkable how little, if any, stretching of the union occurs in cases treated in this way *when care is taken from the outset to secure free movement of the patella upon the femur.*

The same observations apply with equal weight in the case of fracture of the olecranon. You will find upon examination that in the majority of cases of fracture of the olecranon treated by long-continued immobility in splints the detached fragment of the olecranon is practically fixed to the humerus. I do not mean that it is always fixed by bony ankylosis, but it is connected to the humerus by such strong adhesions that it is very difficult to move it at all. Further, you will find that the utility of the limb in such cases is in direct proportion to the mobility of the detached fragment upon the humerus—in fact, the utility of the limb depends more upon this factor than upon the apparent strength of the union. When the fragment is fixed it will be found upon commencing to bend the joint that movement is obtained not by the gliding downwards of the upper fragment upon the humerus, as should be the case, but by a stretching of the union, the fragment remaining fixed; and in such cases, although flexion may be obtained to a great degree, and sometimes completely, extension power is almost, if not entirely, wanting. So much is this the case sometimes in exaggerated cases that although the patient may be able to semiflex the arm or, perhaps, to flex it completely, if the limb is raised above the shoulder or by the side of the head

[1] Lecture I. was published in THE LANCET of June 2nd, 1900, p. 1562.

the forearm falls down almost as in a paralysed limb, in consequence of the triceps having lost its power from the fixation of the detached olecranon to the lower end of the humerus. If in the treatment of such a case trouble be taken during its early progress to constantly move the detached portion of the olecranon upon the humerus by a little gentle flexion and by lateral manipulation all adhesion is prevented and the patient probably recovers with a limb which is practically almost as useful as if there had been no fracture at all—the utility of the limb here, as in fracture of the patella, when the union is fibrous, depending as much or, indeed, more upon the freedom of movement of the detached fragment than upon the actual strength of the uniting medium.

The two great cardinal facts to bear in mind in the rational treatment of fracture of the patella and fracture of the olecranon are these: 1. The avoidance under all circumstances of any chance of the upper part of the patella or of the olecranon becoming adherent to the sub-jacent bone. Such adhesion may be prevented by massage and lateral manipulation combined with gentle flexion and extension, during which the detached fragment is made to move as much as possible with the distal portion of the limb—i.e., with the leg or forearm as the case may be—the lateral movement being the most readily managed and resulting in the least disturbance of the parts generally. 2. All manipulation and passive movement should be preceded by smooth rubbing of the muscles. By this treatment you will in the majority of cases provide the patient with a limb which is useful to an extraordinary degree beyond that which follows provided you do not adopt this plan. I am, of course, speaking generally only, because occasionally a case treated on other methods will leave a sound and good limb, but many of the cases so treated are very imperfect both in movement and in power. When the fracture of an olecranon is treated by wiring, screws, or pegs the same cardinal points must be borne in mind. Massage and passive movement cannot be practised too soon nor can the patient be encouraged too soon to use gentle voluntary movement at the elbow-joint.

I may perhaps be allowed a moment's digression here to explain, in order to avoid any misunderstanding, that the remarks which I have just made must not be held to imply that I have any wish to substitute in a general way treatment by massage and manipulation for the operative measures now so commonly employed in fractures of the olecranon and patella. I am second to none in my estimation of the value of these measures; but there must always remain a number of cases which, for reasons which it would be foreign to my present purpose to discuss, are not suitable for operation—some in themselves, some because the patient does not desire operation, and some in consequence of the circumstances in which the practitioner finds himself being not such as to justify his undertaking operative measures. In such cases intelligent massage and manipulation will produce a better result than any other plan and in many instances will restore the limb to a degree of usefulness which cannot even be excelled by operative treatment.

IMMEDIATE MASSAGE AND MANIPULATION IN DISLOCATIONS.

For the better understanding of the remarks which follow it is necessary to insist upon the following elementary points. If a dislocation be complete in the ordinary acceptation of the term the capsule of the joint must, as a matter of course, be torn, the rent in the capsule being of large or of small extent. The obstacles to the reduction of a dislocation depend comparatively little, as a rule, upon the situation or character of the laceration in the capsule; occasionally only do some of the difficulties met with in attempts at reduction lie with this structure. The real difficulty is for the most part due to muscular contraction—a fact which is amply proved by the manner in which most difficult dislocations will often reduce themselves as soon as the patient is fully anæsthetised. The longer a dislocation remains unreduced the more marked does this contraction of the muscles become and the more difficult is it to remove the bone from its abnormal site. Supposing that a dislocation remains unreduced for five, or six, or eight weeks in a case such as that of the shoulder, physiological shortening of the muscles takes place; and in consequence a reduction of the dislocation by ordinary means may become practically impossible. I mention these facts not because I suppose you are unfamiliar with them, but because I wish to emphasise as strongly as possible the importance of muscular contraction and shortening as the principal obstacles to reduction in the vast majority of the dislocations with which we are ordinarily called upon to deal. For practical purposes the capsule and surrounding bony points may be ignored, since if they afford any obstacle to reduction it is generally secondary to the condition of the muscles. It is further a most important point to bear in mind that under ordinary circumstances after the reduction of a dislocation the retention of the replaced bone in its normal site depends not so much upon the state of the capsule, which in reality has little to do with the matter, as upon the muscles, aided in certain cases by atmospheric pressure. In fact, the question of the healing of the rent in the capsule is of small importance compared with that affecting muscle-waste. The capsule will heal equally well whether the joint be kept fixed in splints or whether it be subjected to passive movement from the first. The muscles about the joint, especially those supplied by the same nerves, waste rapidly if the joint be kept fixed for ever so short a time and if the fixation be persisted in for long periods this wasting may proceed so far as to be incurable. On the other hand, if massage and passive movement be at once commenced then wasting can be entirely prevented. If the muscles are allowed to waste to any great extent, as you can easily see for yourselves by watching an ordinary case, the whole joint becomes loose and flabby. There is no such thing as a primary tonic condition of the capsule of the joint; the capsule of the joint is a passive structure and has no contractile vitality of any sort beyond that which it derives from muscular attachments and expansions. Hence prolonged fixation of a joint after the reduction of a dislocation allows the muscles to waste, which is tantamount to bringing about the precise conditions leading to recurrent dislocation if attempts to obtain free movement are made. The effect of even temporary fixation of a joint in the production of adhesions which have subsequently to be treated, often for long periods, I need hardly, I suppose, impress upon you—although I fancy that if you were to examine a large number of patients who have had dislocations, say of the shoulder-joint, at a long period after the injury, you would perhaps be surprised to find that the percentage of cases in which some stiffness still persists from this cause is considerable. In the practice of the older school of surgeons prolonged fixation of a joint after dislocation was almost universal, the main object being to allow of a firm and rapid union of the rent in the capsule. So much was thought of the value of the healed capsule in retaining the parts in position that the disadvantages of adhesions and muscle-waste were held to be of no account compared with the vital importance of the completely restored capsule. I strongly recommend you to reverse these conditions by concentrating your attention upon measures for the avoidance of adhesions and muscle-waste. Ignore the torn capsule; the rent will heal soundly in spite of any manipulations or movement it may be subjected to in treatment. Ingenious operations which from the nature of things cannot effect material good have been from time to time invented with a view to the cure of recurrent dislocation by shortening the loose capsules—the fact having been overlooked or forgotten that looseness of the capsule is secondary to muscle-waste, which is the real thing to be combated. The only available method by which muscle-waste can be avoided in these cases of dislocation, especially of the shoulder, is by massage, commencing immediately after the reduction of the displacement—smooth rubbing only for the first two days, after which passive movement follows the massage. *This passive movement may be very free in all directions save that which is in the direction of the muscles which tend to waste. For example, in the case of the shoulder, abduction of the arm from the trunk should not be practised for a week or 10 days after the injury, because the strong action of the adductors, unopposed for the time being by the weakened deltoid, tends to displace the head of the humerus inwards.* For the same reason in the first week no *voluntary* movements should be allowed, all movements being *passive*. Treated on these lines any dislocation of a major joint—e.g., shoulder or hip—may be cured in from two to three weeks without adhesions and with no stiffness remaining. All cases of recurrent dislocation will be found to be associated with marked muscle-waste. The cardinal principle in their treatment is in the direction of rectifying the atrophy of the muscles by massage and methodical exercises with or without electricity, and not in the direction of shortening the lax capsule by operation.

The beneficial effect of massage in dislocations is not limited to the treatment after reduction; it is sometimes of great use as an aid to reduction. The following case will serve as an illustration of this point. A highly sensitive and nervous lady, considerably beyond middle age, dislocated her shoulder in a fall which followed a slip on some parquet flooring. There was extreme pain and the muscular spasm was intense, the least attempt to move the parts eliciting loud cries of pain from the patient. Whilst waiting for the arrival of an anæsthetist, as the muscular spasm was so great, I gently massaged the region of the shoulder, upon which the pain seemed soon to be modified and by degrees disappeared. In the course of the rubbing I noticed that the muscles became less hard, and especially I observed that the *hollow tension* of the deltoid was succeeded by a feeling of softness. Seizing the favourable moment I passed my right hand into the axilla and with a sudden outward jerk reduced the dislocation easily (the displacement was sub-glenoid); in fact, had an anæsthetic been administered reduction could not have been more easily effected. In two other cases of dislocation of the shoulder of a similar kind, one being subcoracoid, the other sub-glenoid, I have in the same way effected reduction with remarkable ease. Cases like these show further the point I have already insisted upon—viz., the importance of concentrating your mind upon the condition of the muscles in cases of dislocation.

Before leaving the subject of dislocations allow me again to refer to the question of muscle-waste in these cases because I do not think in some instances it is sufficiently understood. In the case of the fleshy joints—e.g., the shoulder and hip—muscle-waste, unless the massage treatment is adopted, is too obvious to require comment. Wasting in the same manner occurs uniformly in all dislocations, although I hardly think that this is recognised by some people. The wasting, for instance, of the quadriceps in certain conditions of the knee is of common knowledge, but I venture to think that the wasting of the muscles controlling the ilio-tibial band is but little realised. Again, it would at first sight seem almost impossible that any wasting of muscles should follow upon dislocations of distal joints like the phalanges of the finger which are quite remote from muscular bellies, yet in these it will be found if examination be made that there is universally some wasting of the forearm, and further that the permanent sense of weakening which is complained of by some of the patients who have suffered from these injuries can only be rectified by voluntary exercises or by thorough massage of the forearm muscles. The bearing of these points upon the scientific treatment of these injuries is too obvious to require explanation, but it is, I am sure, of much more importance than is commonly thought. It would, of course, be interesting to describe *seriatim* and in detail the management of the various dislocations throughout the body by immediate massage and passive movement, but time will hardly allow of this. I hope, however, that what I have been able to say will be sufficient to indicate the general principles upon which the treatment should be conducted. Its modification to the requirements of the different joints is merely a matter for the exercise of ordinary intelligence.

IMMEDIATE MASSAGE IN SPRAINS, WRENCHES, AND BRUISES.

As in the case with dislocation, as I have endeavoured to explain, the objects to be attained in the treatment of sprains, wrenches, and bruises are the restoration to the normal state by the rapid removal of effused products, the prevention of adhesions, and the avoidance of muscle-waste. Any treatment which fails to obtain these ends is defective. Further, it is, I am sure, undeniable that the only plan of treatment which will attain the desired end with certainty and in a reasonable time is that by immediate massage and very early passive movement—a plan which is, if intelligently used, applicable universally, with the exception, perhaps, of a few special cases.

First, with regard to sprains. For our present purpose by a sprain is meant an injury to a joint, a muscle, or other soft parts by a wrench, a bend, or a twist. There is always some laceration of the tissues but there is no open wound. In the case of a joint the injury always involves some tearing of the fibres of the capsule, synovial apparatus, or cartilage. There is pain of variable degrees and there may or may not be effusion into the joint. Generally, if the sprain is of any severity there is effusion into the joint, if the effusion follows immediately upon the injury it is blood, if it follows a day or two subsequently it is due to synovitis. I must again crave your indulgence for emphasising such elementary points. The occurrence of this laceration in cases of sprain—which means, of course, a subcutaneous wound—led to the faulty practice of former times, which is even now, I fear, far too prevalent, of placing parts so injured for a long period in splints. This is the best possible method for facilitating the formation of adhesions and the perpetuation of muscle-waste, the main object of this mistaken treatment being to allow of the rapid healing of the wounded tissues—a point of comparatively small importance.

In order to make clear the plan of treatment which I use and which I strongly advise you to adopt in these injuries let us take the case of a man who has sprained his knee. At the time of his coming under observation—say a few hours after the injury—the joint is painful, swollen from effusion (probably for the most part blood), and any attempt at movement of the joint is resisted. The first indication is the removal of the effusion. With this object the patient is, if possible, sent to bed and the limb is placed upon a light back-splint—a ham-splint being the most convenient—applied so that free access is left to the joint. Gentle smooth massage over the swollen joint is commenced at once. (In very severe cases this is sometimes resented at first by the patient, whose resentment, however, soon subsides when he realises the soothing effect which the gentle rubbing produces.) In the intervals of the rubbing fomentations of lead and opium may be laid upon the joint; the opium soothes somewhat and the lead hardens the skin a little, which is useful in the subsequent management. From the first gentle passive movement of the patella is used, for the reasons which I have already sufficiently indicated. As soon as the effusion has distinctly commenced to subside, as is shown by the decrease in the tension of the joint, gentle passive movement (flexion and extension) is commenced, and if upon the commencement of the passive movement no increase of effusion occurs the splint is put aside altogether. When the patient comes under treatment immediately after the injury the splint can generally be dispensed with on the third day. With the discarding of the splint gentle massage of the thigh and leg is added to the rubbing of the joint itself, the passive movement and the massage becoming more and more thorough as the effusion subsides. A compress of the kind mentioned may be used in the intervals if it is comfortable to the patient. Treated in this simple way there are few cases of severe sprain of the knee in which the patient may not be getting about comfortably in a fortnight, at the end of which time another fortnight of methodical exercises, either in a gymnasium or by means of a "home" exerciser, will generally complete the cure. I have taken as an example a severe case requiring confinement to bed. The treatment of the milder forms is modified to the necessities of the case, the great points to be borne in mind being the necessity for avoidance of the use of splints after the effusion has commenced to subside, the immediate use of massage to the joint, and early passive movement. In all cases the early movements should be passive—the habit of sending the milder forms of sprains at once to the gymnasium is to be avoided. In no case of sprain should a cure be considered to have been obtained if any sign of wasting of muscle beyond that which comes from mere disuse remains. The longer the time which intervenes between the receipt of the injury and the commencement of the rational treatment the greater is the difficulty in rectifying the muscle-waste with its necessarily concurrent weakness, and in cases in which the parts have been long confined in splints a cure in the true sense is sometimes impossible.

The following points in the carrying out of passive movement in cases of sprain are of some moment. The first movements used should be those of the simplest kind; for example, flexion and extension in the hip or knee, antero-posterior movement in the shoulder, abduction and adduction should then follow, and finally rotation and circumduction in joints permitting of that movement. This sequence, however, is always interrupted for the following reason which is of paramount importance—*the last movement to be practised should be that which, so far as can be ascertained, was concerned in the production of the injury.* Let me make myself clear. Suppose for a moment that a severe sprain of the shoulder has been caused by a fall on the hand or elbow, the arm having been at the time widely abducted from the side—the damage will be probably about the inner aspect of the capsule or under the acromion.

n such a case passive abduction should be the last movement practised, as it would be the movement most likely to irritate the part immediately lacerated or bruised. Although it should be the last movement to be commenced it should not, however, be long deferred, seven days being probably the limit of time which can with safety be spared before its commencement. Again, in the sprain occurring in internal derangement of the knee-joint the injury is almost always caused by either internal or external rotation. In such a case, therefore, the last movement to be practised is rotation. Indeed, it is, speaking generally, better to avoid rotation altogether in that particular class of case.[2]

In sprains complicated by external wound it is clear that the plan which I have been advocating cannot immediately be adopted in its entirety, nor can massage be comfortably practised immediately over the damaged part when the skin is abraded or raw; but in such circumstances massage of neighbouring muscles and passive movement should always be practised, the peculiarities of each case dictating the modifications which are necessary in the application of the treatment.

I had intended giving some details of the treatment of simple bruises by this same plan of massage and movement, but the allotted time has been more than spent. All, therefore, that I can say is that in these cases the method of its application and the objects are the same as those already mentioned—viz., the rapid removal of effusion and the prevention of matting of the injured parts.

In conclusion, allow me to say that I have no desire that the treatment which I have been now advocating should be used to the exclusion of all others. My main object is to urge upon you the desirability of shaking off to some extent the incubus of the traditional routine treatment of fractures and the other kinds of injury of which I have been speaking by prolonged splinting, strappings, counter-irritants, &c, and, unless unavoidable circumstances prevent, to substitute a line of treatment which is, I am sure, rational and will in the end be found, by anyone who will take the trouble to acquire a personal experience of it, to produce results far superior to those obtainable by other plans.

THE PRIMARY DISORDERS OF GROWTH.

BY HASTINGS GILFORD, F.R.C.S. ENG.

THERE is a widespread belief that, apart from its antiquarian interest, medical history is of no practical use. Is not this largely because we do not apply the lessons which that history teaches to the circumstances of the present day? Neglect of the teaching of the past causes us to go astray in two opposite directions. On the one hand we are prone to treat the beliefs of our forefathers with more or less of contempt, while on the other hand we attach so much importance to them that we regard it as sacrilege to question their truth. Nothing, for example, can exceed our disdain of the practice which was in vogue during the early part of the century, yet much of our own practice is founded upon a groundwork which was laid down at the same period, and we are no more inclined to question its stability than we are to doubt the permanence of some stately cathedral.

Now, both these attitudes of mind are undoubtedly wrong. Both are due to a misapprehension of the principles which underlie all history. Perhaps the best corrective to that irreverence of mind which despises all that our forbears esteemed is the thought that this same history tells us beyond all denial that just as we look back upon the medical practitioners and the methods of 100 years ago so will our descendants of a century hence regard us and our methods. We are far too prone to view our work with a satisfaction and complacency which should go only with final achievement. We cannot realise that we are still running our race and are not even within sight of the goal.

We also have to lay it to heart that history teaches quite as emphatically that old-established theories must be constantly tested in the light of more recent days. They are good maxims which assert that we should accept nothing which is based solely upon authority and which bid us to be sceptical even of that of which we are most sure. The fact is, that we of the present day suffer from our very nearness to the work of our time—we have not the immense advantage of being able to look upon its facts and circumstances from a distance. Our ideas suffer from a want of perspective, and we are therefore apt to attach far too much importance to certain particulars and far too little to others. There is no better example of this form of distortion and of its possible consequences than the absorbing attention which is now being given to the causes and pathology of one class of diseases and the almost equal neglect which is meted out to others. Much good work has been done of late in the investigation of the influence of certain fungi in the production of disease, but there are indications that we are already losing all sense of proportion and are attaching too much importance to these fungi in their relation to etiology and pathology, and that we think far too highly of the effect of their destruction in the eradication of disease. There was at one time a sanguine hope that a method had at last been found whereby the bacillus of phthisis could be killed in the body without the destruction of its host. It was thought that the discovery had actually been made and that it was "the greatest medical discovery of the century"; but we have every reason to be thankful that these expectations were disappointed, for it is difficult to conceive of anything that would have been more disastrous to human health and happiness. Nothing is more certain than that these fungi, bad as they may seem in the individual, are salutary, and that, on the larger stage of human affairs, they play their allotted part wisely and well. They are as essential to our welfare as are decay and death, wherever they are found. Now, in these days the direct treatment of the fungus of phthisis is no longer the chief object of the physician, but it plays a secondary part, subordinate to the far more important clinical measures of fresh air, sunshine, regulated exercise, and food. There can be no doubt that could some method be found of safely and directly killing the fungus of phthisis, or of cholera, plague, or other disease, we should be inclined to rest content while the conditions which favour its growth would go on unheeded. We should in each case cast out one devil and leave a state of affairs which would favour the entrance of seven other devils far worse than the first. Yet there is still the same eager pursuit of the germs of disease and the same elusive hope that we shall gain by their destruction. It would be absurd to deny that good arises from this pursuit, but, unfortunately, there is evil as well; and not the least is the comparative neglect of the study of other diseases and their origins, some of which are more important and more worthy of investigation. Hence it has come to pass that while on the one hand we are rapidly gaining acquaintance with the appearance and habits of the parasites of phthisis, enteric fever, cholera, the plague, and other bacterial diseases, we know almost nothing of the factors which are responsible for the appearance of a large number of other disorders. Some of these, such as myxœdema, osteitis deformans, and acromegaly, have not long been brought to light, while others, and among them cirrhosis of the liver, ichthyosis, and primary Bright's disease, are comparatively old. With few exceptions they are regarded as diseases which have been well discussed by great authorities who are still living or are but recently dead, and it is commonly supposed that there is not much more to be learned about them. But it is contended that our knowledge of these diseases is by no means exhausted; moreover it is believed that their study will throw light on the causes and nature of innocent tumours and cancers and on the conditions which underlie the appearance of some of the bacterial diseases. In fact, there is reason to believe that their relation to some of the bacterial diseases is as that of the horse to the cart, and that they ought, therefore, to take a corresponding place in order of investigation. The most important of the diseases referred to are as follows, viz.: the different forms of leukæmia and primary anæmia; the muscular dystrophies; the scleroses of the brain and spinal cord; cirrhosis and acute atrophy of the liver, and primary Bright's disease; idiopathic obesity and emaciation; myxœdema and Graves's disease; Addison's disease, acromegaly, and gigantism; scleroderma and ichthyosis; and osteitis deformans and osteomalacia.

It is true that theories are not wanting to account for the appearance of these diseases, but as a rule they are indications rather of the existence of a natural horror of an

[2] For details of the author's treatment of these cases see THE LANCET, Jan. 6th, 1900, p. 6.

etiological vacuum than of a serious attempt to deal with the question which they are supposed to settle. This may be said, for example, of three of the most popular of these hypotheses—namely, the inflammatory, the bacterial, and the nervous. In nearly all cases one or other of these theories is torn out of its proper setting and forced to do duty in a way which is foreign to its nature. Each when applied to any one of these disorders is as a round cork to a square hole: it may be made to go in but will not fit.

Now it is the object of this paper to show that all the diseases in question belong in reality to the same type or group. At first this appears to be quite impossible, seeing that they differ so widely that they do not seem to have anything in common; but on subjecting them to that form of inquiry which has for its object the sifting of principles from details, it will be found that these differences, great as they may appear, are not in reality such as separate classes or orders, but only genera or species. They are in all cases due to differences of form, use, or age of the organ affected, and to these alone. They are secondary or accidental, and not primary or essential. If we put these accidental differences on one side and keep in view only those which are essential it will be found that the diseases in question resemble each other and differ from all other diseases in the following particulars.

A. Form.—The form which is assumed is invariably one of four kinds, the differences between them establishing the genera. The organ affected shows either: (*a*) hypertrophy (enlargement with increase of function), as of the thyroid gland in Graves's disease and of the bones in gigantism; (*b*) degenerative hyperplasia (enlargement with destruction of function), as of the thyroid gland in goitre, the bones in osteitis deformans, the blood in leukæmia, and the lymphatic glands in Hodgkin's disease; (*c*) hypoplasia (simple defect of growth), as of the brain in microcephalism and of the kidney in congenital "atrophy" of that organ; (*d*) degenerative hypoplasia (degeneration and wasting), as of the anterior horn of grey matter of the spinal cord in progressive muscular atrophy and of the liver in acute atrophy of that organ.

These forms may be still further reduced to two. In one (hypertrophy and hypoplasia) the constituent elements remain unaffected in proportion and quality though the organ itself may be either larger or smaller; in the other (degenerative hyperplasia and degenerative hypoplasia) together with alteration in size of the organ involved the constituent cells are degenerated, and running with this degeneration is more or less increase of tissue of low type. Some of the conditions included in the first of these two are on the boundary line between health and disease, as in hypertrophy of bone (gigantism), muscular hypertrophy, and obesity. While on the one hand they merge into conditions of health, on the other hand they shade off into the next group and show an especial tendency to degenerative changes. The following group characters must therefore be understood to apply more particularly to those diseases which are distinguished by degenerative atrophy or excess, though all diseases share in them more or less.

B. Functional characters.—1. All the diseases under consideration are *sporadic*, though some may be also endemic. Among the chief of these latter are goitre and osteomalacia. Others show the same tendency in a minor degree, as, e.g., osteitis deformans and pernicious anæmia.

2. All are *idiopathic* in origin, using the word in its widest sense as signifying, not that they have no cause (which would be absurd) but that their causes are not recognised or are unknown. This is true of every one of them, for though many diseases undoubtedly owe their appearance to certain more or less well-defined causes yet in no case can it be said that these causes account for all cases of the disease. Moreover, in those instances in which these proximate causes are so obvious as to admit of no question, they must still be regarded as idiopathic, since there is always some remote but necessary cause at work, of the nature of which we have to express our ignorance. Thus we well know that cirrhosis of the liver is produced by the action of alcohol; yet it is quite as certain that behind this there is an ultimate cause with the nature of which we are unacquainted and which is still more important than alcohol, for it is only in this way that we can account for the fact that hard drinking will produce the disease in one drinker and not in another, or that cirrhosis may occur in a teetotaler and not in a drunkard. On the other hand, no disease is truly idiopathic, in whatever sense the word is used, for not only must each have some primary cause, but, as a rule, some secondary influence can also be traced in its production. Thus, pernicious or idiopathic anæmia, notwithstanding its name, is undoubtedly sometimes partly caused by influences which have an exhausting effect upon the body at large and upon the blood in particular. Depressing mental emotion, excessive bleeding, insufficient food, and frequent child-bearing may each be regarded as a cause of pernicious anæmia. In most of these diseases a multiplicity of secondary causes, differing more or less in kind, can be traced, and this fact by itself at once shows that there is some one unknown, but essential, cause at work, for only on this ground can it be explained why different actions should produce the same effects.

3. All are *progressive* in their course, though this course is, in most cases, liable to interruptions. Periods sometimes occur during which the progress of the disease is arrested or positive improvement takes place. This is especially the case with pernicious anæmia, osteomalacia, lymphadenoma, the leukæmias, cirrhosis of the liver, granular kidney, Graves's disease, and disseminated sclerosis and other scleroses of the spinal cord, but it is also noticeable in other diseases of the group. These periods of abatement or arrest are irregular in their appearance and are more marked in some cases than in others.

4. All are *pernicious* in their results—i.e., when well established their course terminates only with the destruction of the part affected or in death. Exceptions to this rule are met with in some of those affections which are most exposed to external influences, such as scleroderma and ichthyosis, and, in a less degree, in other diseases. It is probable that in no case is the disease absolutely hopeless, though in most we are justified in pronouncing it to be so.

5. No remedy has been found of any certain effect in any one of them with the exception of the skin diseases. They are *incurable* by drugs. A modified exception must, however, be made in favour of three or four drugs, one of which is arsenic, which has been found to do good in pernicious anæmia, in the allied anæmias and leukæmias, and in some other diseases. Another is extract of the thyroid gland, which is of use in reducing obesity, goitre, and some other enlargements. Iodide of potassium and some of the salts of mercury may also have an influence in the direction of cure.

The diseases of the group have also certain other features in common.

6. They show peculiar liability to attacks of inflammation. This is most evident in the various forms of leukæmia and in fibrous degeneration of the liver, kidneys, lungs, prostate, and ovaries.

7. There is also close affinity between many of these diseases and the infective granulomata. This is especially shown in fibrous degeneration of the lungs, in lymphadenoma, and in local gigantism of the hands or feet. So close is this relation in certain cellular diseases of the adrenal and pituitary bodies that it may be almost impossible to say in a given case whether we have to do with a degenerative hyperplasia or with one form of granulomata or another. Sometimes, moreover, syphilis or tubercle may pass by almost imperceptible steps into hyperplasia or atrophy, as when it produces fibrosis of the lungs or liver, or when syphilis in its congenital or tertiary form affects the nervous system. It is probable that every one of the diseases of this group may be either produced or successfully imitated by syphilis alone.

8. They are all closely related to the innocent tumours and to the cancers. This is shown in the following ways—viz., (*a*) By their occasional occurrence together in different parts of the same body, as when fibrous or fatty tumours are found on the trunk of a patient affected with local giant growth of the extremities, or when myeloma occurs with Hodgkin's disease or with goitre,[1] or sarcoma of the stomach with osteitis deformans. Cancer of the breast, the rectum, or other part sometimes also occurs in patients affected with fibrous or cystic disease of the ovaries, or tumours of the suprarenal capsules (two cases) with sexual precocity.[2] I have seen the conjunction of idiopathic obesity with a cartilaginous outgrowth and with a third mark of degeneration—viz., diabetes. Instances are also reported of the association of splenic leukæmia[3] and of Hodgkin's disease[4]

respectively with carcinoma. Israel and Leyden[5] give details of a case which they believe to be one of mixed splenic anæmia, pernicious anæmia, and multiple sarcomata, but this opinion cannot be considered conclusive, for no microscopical examination of the blood appears to have been made during life. They refer to some cases reported by Grawitz in which sarcoma seems to have occurred with pernicious anæmia, and similar cases by Ehrlich and Litten are also mentioned. None of these cases, however, is of recent date. (*b*) More often the relation is indicated by the direct origin of tumours from parts affected with these diseases, as when fibrous or fatty tumours spring from giant extremities, tumours of bone, cartilage, marrow or sarcoma tissue from affections of bone (osteomalacia or osteitis deformans), carcinomata or sarcomata from cirrhosed livers, from cystic ovaries or breasts, or from goitres, and when fibro-myomata spring from enlarged prostates. (*c*) Innocent tumours and cancers also show a resemblance in having no known origin and in being pernicious and progressive, but irregular in rate of growth, incurable, and resistant to medicinal treatment.

9. There also appears to be some connexion between these diseases and congenital excesses and defects. This is shown (*a*) by the occurrence of a congenital malformation and one of these diseases in the same individual. As a rule the two occur together in the same organ or organs, as when macrodactyly affects a hand with webbed fingers (two cases)[6] or when misplaced or malformed kidneys, breasts, or testicles become the seat of fibrous or cystic disease. Dr. Hale White[7] gives a good instance of this combination of malformation with fibrous metaplasia. The patient was a child, aged nine years, each of whose kidneys was cut into by a band of fibrous tissue in such a way as to constrict off one-third of its substance. The smaller portion of each kidney, so constricted, was affected with cirrhosis. There was also an associated "hypertrophic" cirrhosis of the liver which was not due to alcohol. In another case we find cirrhosis of the liver occurring in an organ in which the left lobe was rudimentary.[8] The left kidney and suprarenal capsule were absent. Instances are also not very uncommon in which one organ is misplaced or malformed while the other is fibrous or cystic. At other times the malformation and degenerative disease occur in different organs, of which two instances have just been given and many others are reported. Thus Dr. Carrington[9] writes of a case of pernicious anæmia in which there were also various congenital deformities of the genito-urinary organs of the left side. Such cases as that of the association of malformation of an eye with hypertrophy of the sexual organs, of amyelus or atrophy of the thyroid gland with ichthyosis, of congenital heart disease with congenital splenic leukæmia,[10] or of retinitis pigmentosa with lymphadenoma,[11] are by no means uncommon. Sometimes the association occurs so often that it has become an item of ordinary information, as when polydactylism occurs with a particular form of idiopathic obesity, deaf-mutism with goitre, or cleft palate with cretinism. (*b*) At other times they are associated in different members of the same family. Of this, too, there are many instances, though it cannot be said whether they are sufficiently numerous to establish a connexion between them from this association alone. (*c*) Like congenital malformations, also, they show hereditary tendencies or occur as family diseases. This heredity may be direct or indirect. There is good evidence that *direct* and family heredity is sometimes shown by splenic leukæmia, osteomalacia, granular disease of the kidneys, goitre, Graves's disease, scleroderma, ichthyosis, and various fibrous degenerations of the muscular and nervous systems. There is also reason to believe that osteitis deformans, Addison's disease, lymphadenoma, and cirrhosis of the liver may be transmitted in the same way. *Indirect* heredity is that form of heredity which is manifested by the occurrence of one or more diseases of the group in a family of which other members are affected with some disorder which is recognised to be hereditary. Thus there are many instances on record of one or more members of a family being the subject of diabetes, hare-lip, goitre, polydactylism, or other stigma of a transmissible nature, while others are affected with some disease of the group now being referred to. This association when it takes place is nearly always alluded to incidentally. Probably many other cases occur in which it is not thought worth while even to make mention of it, the connexion between the different diseases being thought to be too remote. (*d*) They also behave like congenital malformations in showing a tendency to occur together in the same individual. Moreover, like them, they as a rule affect those parts which are related physiologically or by continuity of tissue. Thus hyperplasia commencing in one hand or foot is prone to extend to the rest of the limb or to the other hand or foot. In granular disease of the kidney both organs, as a rule, are involved, though one may be much worse than the other, and it is rare not to find other parts of the cardio-vascular system affected as well, while cirrhosis of the liver is a frequent concomitant. Hyperplasia of the lymphatic glands, in the same way, soon leads to degenerative changes in the blood or spleen. In the same way, also, hypoplasia or hyperplasia of deep layers of the skin sometimes leads to corresponding defect or excess of the underlying connective tissues, or even of the bones, as in facial hemi-atrophy and hemi-hypertrophy. There is also reason to believe that degenerative hyperplasia of the bone marrow and bone (osteomalacia and osteitis deformans) may occur together. Many other instances occur. Thus splenic leukæmia may be associated with chronic Bright's disease,[12] splenic anæmia with cirrhosis of the liver,[13] and primary uncomplicated splenomegaly with cirrhosis of the liver.[14] (*e*) Or they may occur in different members of the same family. Thus among the many cases which are reported in different journals we find one in which one member of a family had muscular dystrophy, another cirrhosis of the liver, while yet another died from granular disease of the kidneys. In another case one had cirrhosis of the liver and another disseminated sclerosis. Sänger,[15] in describing a case of congenital splenic leukæmia, mentions that the mother was affected at the time of the child's birth with chronic Bright's disease. I myself was recently present at the post-mortem examination of a child (a patient of Dr. Francis Hawkins) who had died from cirrhosis of the liver and in whom the spleen was found to be large and in a more advanced stage of fibrosis than the liver. A brother of this patient was suffering at the time from muscular dystrophy. No cause could be found for these diseases. Many other similar cases might be mentioned, but perhaps the most striking is one which is incidentally referred to by Professor Clifford Allbutt,[16] who says that he was "once called in consultation to a father and three children, whose maladies were as follows: carcinoma, lymphadenoma, pernicious anæmia, and pseudo-hypertrophic palsy." All these are examples of heredity showing itself in an indirect manner. They furnish evidence as to the unity of the different diseases. Other instances will be referred to presently.

SIGNIFICANCE OF ASSOCIATION.

The association of these diseases in the same family or the same individual has hitherto been held to be due either to mere coincidence or to the one disease being the direct outcome of the other. The latter view may, however, in most cases be at once dismissed, seeing that it is usually founded on the fact of association alone and has no other basis. In regard to the former view it is obvious that it cannot be entertained if in the case of any given disease it can be shown that those affected with it are far more subject to either of these diseases than are the population in general. Due allowance in such cases must, of course, be made for the action of some common exciting cause—such as alcohol or syphilis. As a matter of fact it is widely recognised that after making such deduction certain of these diseases occur in association much more frequently than can be explained on the score of mere chance. Under these circumstances the aid of a "diathesis" has been called in and an individual affected with degenerative hyperplasia of two or more organs, such as the lungs, the liver, and the spinal cord, or the kidneys, is said to be suffering from the effects of a "fibroid diathesis." In other words, it is recognised that behind these associated diseases there is some dyscrasia which predisposes the tissues to mixed overgrowth and degeneration.

This is, in fact, identical with the view which is now being put forward. Here, however, it is widened in scope so as to embrace degenerative overgrowths of all organs and tissues. It includes not only morbid excesses of growth, but defects, especially where they are combined with degeneration, and these excesses and defects may date from all periods, either before or after birth.

But although it is recognised that there is some common factor underlying the appearance in the same person of such prevalent diseases as cirrhosis of the liver and granular kidneys, the same cannot be said of the rarer of the diseases under consideration. Yet the statistics of some of the less common of these diseases seem to tell the same tale. Thus, in writing of splenic leukæmia Sir William Gowers [17] says that among 111 cases the state of the kidneys was referred to in 62, and that in six of these they were affected with Bright's disease; while among 109 cases of leukæmia there were three instances of cirrhosis of the liver. Now the percentage of liver and kidney diseases here is far higher than it is among the healthy, yet it is quite possible that there was some common exciting cause, such as alcohol or syphilis, which accounted for the association, though Sir William Gowers himself says that it was accidental. The same explanation may also be given of the conjunction in the same person of Addison's disease and cirrhosis of the liver (Dr. Leva [18] and also Dr. Carrington [19]), of Addison's disease and chronic Bright's disease (Dr. Thompson [20]), or of pernicious anæmia and goitre.[21] But it is evident that the more these instances multiply and the rarer the diseases themselves are, the less likely it is that their conjunction is due to mere chance. Thus in a case of Addison's disease in a man, aged 36 years, which was carefully examined by Dr. Bergtold,[22] it was found after death that there was not only the usual lesion of the suprarenal capsules, but that there was also slight emphysema of the lungs, cirrhosis of the liver, fibrosis of the spleen, chronic Bright's disease of the kidneys, and obliterating degeneration of the arteries. The diseased capsules were examined for tubercle bacilli, but none was found. Now, it is true that this man "had been in the habit of drinking a great deal of beer," but nevertheless the bare fact of the occurrence of such a number of degenerative diseases in one man goes a long way towards proving their family connexion and dependence upon some remoter origin than beer. Perhaps even more may be said of the association of two such rare diseases as Hodgkin's disease and osteomalacia (Dr. Goodhart [23]) or of Graves's disease and osteomalacia.[24] Equally significant is the occurrence among different members of the same family of Addison's disease and Graves's disease (Dr. Hale White [25]), and it would be contrary to all the rules of evidence to believe it possible that the before-mentioned instance of the occurrence of carcinoma, muscular pseudo-hypertrophy, pernicious anæmia, and lymphadenoma in a father and his three children respectively (Professor Clifford Allbutt) should have no other explanation than that of fate. Finally, some diseases are associated so often that there seems to be no possible escape from the inference that there is some common but remote factor which connects one with the other. This may be said, for example, of the conjunction of cirrhosis or atrophy of the stomach and intestines with pernicious anæmia, of fibrous degenerations of the spinal cord with pernicious anæmia, of similar degenerations of the brain and spinal cord with osteomalacia, and perhaps Dr. R. Saundby's [26] cases of hereditary enlargement of the spleen with atrophy of the suprarenal capsules. In each of the first three of these instances the usual explanation is that the association is due either to the one disease being the direct cause of the other, or to both being the result of the same poison acting in different ways on different parts. The view which is held here is that they are related to one another as cleft palate is related to club-foot, that they are the expression of some intrinsic and unexplained anomaly of growth or malformation, and that, like all other malformations, they tend to occur in different parts of the same body and in different members of the same family.

Beyond what has already been said, evidence as to the class unity of these diseases and as to their nature is furnished by the occurrence of certain links which connect two or more of them together. Thus diabetes, which is one of these links, is found in association with cirrhosis of the liver, idiopathic obesity, splenic leukæmia, pernicious anæmia (Osler), osteomalacia, acromegaly, Graves's disease, general paralysis, and tabes dorsalis. Goitre is another such link, and scleroderma another. These and chronic Bright's disease, or "dropsy," or "liver disease," are not infrequently found as comcomitants or as family complaints in the clinical reports of the rarer diseases.

Some of the associations which have been mentioned are by no means convincing and are doubtless capable of explanation on other grounds than that of a common origin of the associated diseases in a depravity of growth. But it must be insisted upon that the subject is not like a chain whose strength resides in its weakest link. It is like a collection of sticks, some of which may be mere twigs and easily snapped when they are taken separately, but when bound up together they form a bundle which cannot so readily be broken. It must be recognised that that the subject is one which is strengthened by everything that supports it, however weak it may be. Taken as a whole, in this way the facts are consistent with the view that the diseases which have been mentioned owe their origin to the same ultimate cause acting in the same way upon different tissues. They form a group which is closely connected with that of the granulomata and the tumours, and which differs in no essential particular from that which is formed by congenital malformations, but differs in every important respect from all other groups.

RELATION TO OTHER DISEASES.

Mixed forms.—This group of primary growth diseases comes in contact with other groups in many directions. Thus it is mixed more or less with other groups in rheumatoid arthritis, in the infective granulomata, and in inflammation. Hereditary and tertiary syphilis in particular sometimes give rise to such overgrowth and degeneration as may be indistinguishable from that which is idiopathic. This is the case, e.g., in some instances of locomotor ataxia, of general paralysis, and of leucoplakia of the tongue.

Relation to inflammation.—Inflammation runs by such imperceptible degrees into degenerative hyperplasia that instances occur of which it is almost impossible to say whether they are more inflammatory or more hyperplastic. This is well shown in a case which I once reported,[27] in which these two processes also merged into that of new growth. In this case a concretion in a vermiform appendix gave rise first to inflammation with the formation of pus and then to a large hyperplastic swelling which finally ended in sarcoma. As a rule, however, inflammation, when it arises in the course of lymphadenoma, splenic enlargement, cirrhosis of the liver, or any other of the group, is not primary but is an addition to the morbid process; or, at most, it acts but as a secondary or exciting cause. It then signifies no more than that tissues affected with overgrowth and degeneration are thereby rendered more vulnerable to those micro-organisms which give rise to inflammation. But though inflammation and hyperplasia are closely connected they are in reality very different processes. Inflammation is essentially a protective and *destructive* process; whereas the process which gives rise to scleroderma, muscular pseudo-hypertrophy, Hodgkin's disease, osteitis deformans, and other diseases of the group, is essentially self-contained and *constructive*. The one has a motive, the other has none.

Relation to malformations.—While degenerative hyperplasia and inflammation are distinct from one another the same cannot be said of hyperplasia and the malformations, or errors of development. Everything that is known of these two goes to prove that they are identical. It is so usual to associate developmental errors with fœtal life that we sometimes forget that the processes of growth and development, with the possibility of running too far or in wrong directions, do not stop at birth, but continue even up

to middle age, and then only to give place to processes which end in decay. During the whole of this period of the rise and decline of life growth may go astray, and the disorders which show themselves at different periods are necessarily tinged with the characters of the particular period in which they first appear. Thus we can hardly expect that a mistake in the processes of growth originating in the first month after birth will show itself in exactly the same way as one which takes place in the first month of fœtal life, nor ought we to suppose that a fault of similar nature starting in infancy will lead to the same results as one which first shows itself in middle or old age.

The differences that may in this way arise at different ages may be formulated as follows. Errors of growth taking place in early life may be expected to differ from those which first appear at a later age. 1. They will differ in being more rapid, in accordance with the greater rapidity of the processes of natural growth and development. 2. They will differ in being more definite and complete, owing to the same cause. 3. They will differ in being more widespread, for the same reason and because of the comparative smallness of the area to be covered. 4. They will differ in being more often multiple, because an affection taking place in a plastic tissue will naturally tend to implicate each of the different organs into which that tissue is moulded. 5. Errors of development occurring in early life must also be more often hereditary or family diseases, because it must of necessity happen that the stronger the taint the earlier will it tend to show itself. 6. Also in the case of double organs the more complete will be the compensation when only one is involved. On the other hand, when single organs are diseased the more profoundly will all those tissues be affected which are dependent upon them. 7. As a rule, the earlier in life the disease occurs the more defined will be its cause. Those malformations which occur in fœtal life we have no hesitation in calling idiopathic; those which first show themselves in infancy or childhood (e.g., cretinism, pseudo-hypertrophic paralysis, cirrhosis of the liver, or granular kidneys) we suspect may have some other cause; but those which first appear in adult life, such as myxœdema, cirrhosis of the liver, granular kidneys, splenic leucocythæmia, or Hodgkin's disease, we attribute to many causes. These etiological differences arise from the fact that before birth influences which can be brought to bear upon processes of growth are so scanty that, with the exception of syphilis and alcohol, they are a negligible quantity. But in later life there are many influences which may affect growth adversely and play their part in the production of disorder.

If we keep in view such considerations as these we find sufficient explanation for the fact that some diseases which were at one time thought to be distinct are now known to be in reality the same diseases modified by age. Thus, the skin disease of the harlequin fœtus is now recognised to be the same disorder as the ichthyosis of the youth or the young adult. It is the same disease, but more rapid in its development, more definite and complete, covering a wider area, more often hereditary, and affecting the functions of the body more profoundly. Goitre and arrest of growth of the thyroid gland in the fœtus give rise to a condition which is so different from the cretinism of the infant that it is sometimes looked upon as a different disease and called fœtal rickets. Cretinism of the infant, again, was at one time regarded as a totally different disease from the cretinism of the adult, and it was for this reason that the latter was so unfortunate as to receive a different name. It is now clearly recognised that these three diseases are but instances of the same disease affecting people of different ages. Myxœdema is the same as congenital and infantile cretinism, but is slower in its appearance, less definite and complete, less hereditary, and less disastrous in its effects. All these differences are due to the fact that in one case it first shows itself in an individual who has reached an age when all the processes of life are more subdued, while in others it acts upon the body at times of life when changes are rapid.

In the same way it may be shown that scleroderma, primary lymphatic enlargements, cirrhosis of the liver, granular kidneys, hyperplasia of bone, and similar affections of other organs are sometimes so modified by age that at different periods they may appear to be different diseases. But by making allowance for the effects of age and by tracing disease step by step in different cases, from fœtal life or early infancy to its appearance in adult life or middle age, we find that there is no gap between the conditions we meet with in early periods of life and those which we meet with in the later periods. In this manner we can trace, for example, an unbroken connexion between the granular kidney of the adult, and the absence, or mere fibrous vestige, of that organ which is sometimes met with in the fœtus; between complete absence of a thyroid gland and a fibrous goitre; between an atrophied suprarenal body and one which is cystic, fibrous, or "tubercular."

PATHOLOGY.

These facts and deductions enable us to understand the nature of the morbid process with which we are now dealing. They show that the four different forms which were referred to at the outset are but modifications in rate of growth or maturity. Simple excesses and defects of growth (hypertrophy and simple hypoplasia) are abnormal manifestations of the developing stages of tissue life, and may or may not terminate in premature degeneration. Degeneration and degeneration with overgrowth (degenerative hypoplasia and degenerative hyperplasia) are disorders of the declining periods of tissue life, and at whatever age they occur may be regarded as manifestations of local senile decay or of that which is equivalent to it. In no other way can the anatomical and clinical features of these diseases be accounted for.

Further evidence of the nature of these diseases is furnished by comparing these growth diseases with normal growth.

1. The clinical characters are such as we might expect to find in a primary perversion of growth. Thus the diseases are sometimes inherited because peculiarities of normal growth are to some extent heritable. They are progressive and remittent because natural growth is progressive and proceeds, not with absolute regularity, but by successive impulses, alternating with periods of comparative quiescence. They are pernicious and incurable for the reasons that healthy senile changes terminate either in complete extinction of the function of an organ or in death, and no one has yet been able to permanently arrest the progress of old age.

2. That they are disturbances of growth is also indicated by the way in which they are affected by those changes which influence the rate of normal growth. Hence they are peculiarly liable to appear during fœtal life, early infancy, puberty, and the menopause, and often originate in, or are improved or aggravated by, pregnancy and the puerperal state. Chronic Bright's disease, pernicious anæmia, and other primary anæmias and leukæmias, osteomalacia, Graves's disease, goitre, acute yellow atrophy of the liver, and Addison's disease are especially implicated in the physiological rise and fall of growth and nutrition which are incidental to child-bearing and the puerperal state, and such a fact as this is of the greatest significance in its bearing on the nature of these diseases.

3. The two kinds of degenerative changes (degeneration and degenerative overgrowth) are identical in nature, if not in quantity, with those which occur in organs affected with senile decay. Thus in the case of the liver granular and fatty degeneration of liver cells sometimes takes place in the old of exactly the same character, though less in quantity and intensity, as that which is found in "acute atrophy." Moreover, there is often decided increase in the quantity of connective tissue in old livers, like that which is sometimes so excessive in cirrhosis; and we may speak in a similar manner of the kidney, spleen, bone, and other organs. Anatomically, in short, degeneration, and degeneration with overgrowth, are exaggerations or caricatures of that which takes place physiologically in old age.

4. Moreover, all those factors which help to give rise to leucocythæmia, granular kidney, acromegaly, pernicious anæmia, and other disorders of their class are essentially of a depressing or ageing character. On the contrary, all those factors which have any influence in delaying the progress of these diseases have actions which are physiologically of the opposite nature. Hence, on the one hand, we find that anxiety, grief, and other depressing emotions, low-lying malarious districts or sunless valleys, repeated pregnancies, insufficient food and clothing, frequent losses of blood, syphilis, alcohol with its offspring gout, and old age itself, all act as causes of these degenerations; and probably nothing has been left outside this list that is of any consequence. All are debilitating and depressing, and the only one to which exception might

be taken on this score is, perhaps, the worst offender of all. I allude to alcohol. It both stimulates and narcotises, both elevates and degrades. It narcotises or depresses all the higher functions of the body and of the mind and lessens the acuteness of the sensations and perceptions. At the same time, it not only impairs functions but disturbs them. It acts upon one part more than another. It diminishes the influence of the inhibitors or controllers and thus indirectly stimulates those functions and qualities which it is their office to control. It stimulates also by dilating the blood-vessels and accelerating the action of the heart. But the action is that of a drug and not of a food: it is pathological and not physiological. This action, which is obvious when alcohol is taken in great excess, differs only in degree from that which is manifested when it is taken in small doses. A stimulant-narcotic action of this character is just that which is best calculated to bring about mixed overgrowth and degeneration and it amply accounts for the disastrous and paramount influence which is played by alcoholic excess in the production of cirrhosis of the liver, granular kidneys, and fibrous degenerations of the brain, lungs, and other organs. On the other hand, the only remedies which are of any use in delaying the progress of these diseases have in health an "alterative" effect which is of an opposite character to the above. These remedies are, among drugs, arsenic, mercury, the iodides, and thyroid extract; and, among hygienic measures, fresh air, sunshine, bracing climates, electricity, massage, good food, and congenial occupation and lively society.

5. Another feature of the degenerative diseases which points to their being of a senile character is their proneness to set in at times of life when the organs they affect are becoming extinct. Thus, myxœdema, though it may appear at any age, is prone to first show itself in women at the time of the menopause, whereas Graves's disease, which is a true hypertrophy of the thyroid gland, generally sets in during early adult life. Osteomalacia appears, as a rule, in women in the prime of life, at a time when the activity of the bone marrow is on the wane, while osteitis deformans does not show itself until middle age or old age, when the shafts of the bone usually first show signs of degeneracy. Prostatic enlargements generally first give rise to trouble between the ages of 55 years and 60 years, when the male sexual organs are becoming extinct.

6. These diseases also resemble senile conditions in their liability to become the seat of innocent tumours and cancers. Thus, degenerative hyperplasias of the stomach, pylorus, breast, tongue, thyroid gland, liver, bone marrow, and shafts of the bones, are all prone to give rise to innocent or malignant tumours. Of these diseases it is noteworthy that degenerative hyperplasia of the shafts of the bones (osteitis deformans) is far more often associated with malignant disease than is similar hyperplasia of the marrow (osteo malacia). This probably arises from the fact that osteitis deformans does not appear until late in life, when there is a double proclivity to the formation of cancer, the special proclivity of the disease being added to the general proclivity of old age.

Notwithstanding all that has been said, it is by no means certain that it is correct to speak of organs, the seat of degeneration or degenerative hyperplasia, as being affected with premature old age; for, as a matter of fact, exactly the same effect might take place as the result of mere defect of development. We might very well suppose that when an organ has been arrested in the course of its development those influences which give rise to growth or nutrition, though insufficient to produce or maintain cells of higher type, may yet be amply sufficient to lead to overgrowth of cells of a lower order. It is possible that we may in this way account for the fact that in these diseases we have not only degenerated cells, but embryonic cells, as in the large white kidney of Bright's disease, in the liver affected with pseudo-hypertrophic cirrhosis, in the bone marrow in osteomalacia, and in the blood in pernicious anæmia. On the other hand, it is conceivable that a senile change taking place in youth may be expressed in this same manner. We may well imagine that it may be attended, not only with considerable overgrowth of tissue of low type, but that there may also be some attempt at progress or repair due to infusion of new (embryonic) cells into the part affected. All that we are justified in saying is that the diseases which have been discussed are not primarily due to the action of any external or internal agent with which we are acquainted. They are further distinguished by the anatomical appearances of degeneration and atrophy of tissue of higher type with overgrowth of tissue of lower type; by the clinical features of sporadic origin, progressive but interrupted course, pernicious effects, and resistance to treatment; by showing as a rule some hereditary tendency; and by being influenced for the worse by certain depressing agents and conditions and improved by others which have the opposite physiological effect. They are especially liable to inflame, have near relations with the infective granulomata, and constitute favourable soil for the growth of innocent and malignant tumours. In these and other respects they show that they are malformations or errors of growth produced either by defective development or premature senile decay.[28]

(To be continued.)

ON THE RELATIVE VALUE OF SYMPTOMS OF ACUTE PERITONITIS.

BY E. STANMORE BISHOP, F.R.C.S. ENG.,
HONORARY SURGEON TO THE ANCOATS HOSPITAL, MANCHESTER.

ANY operating surgeon must have found great differences of opinion existing amongst practitioners as to the presence or absence of acute peritonitis in cases where his interference is required. Why should this difference of opinion exist? Is it that peritonitis itself differs in different patients, or is it not rather due to the vague teaching to be found in text-books and in lectures on the subject? I believe that the latter reason is the true one, and yet the question is an extremely simple one. It is at the same time a most important one to settle and to settle quickly. In the old days the supervention of peritonitis was held to be tantamount to a sentence of death. That is not by any means the case at present. By opening the abdomen and free flushing with saline solution, accompanied or not by incision and emptying of the small intestine, some lives have been saved, but the symptom may be due to some mechanical condition which an intraperitoneal operation, if done early, may easily put right and peritonitis be averted; whilst if is deferred, under the erroneous impression that peritonitis is present alone, such delay may bring about the very condition which has been believed to exist and the complication of both, together with the exhaustion produced during the time which has elapsed, may render the chances of any effective interference hopeless, or at least extremely slight. Given a patient complaining of sudden and great pain in the abdomen we should be able to say at once and without hesitation whether he or she is suffering from acute peritonitis or not. Can we do so?

Let me collate a few authoritative statements from various sources. Spence[1] gives as symptoms of this condition "great pain, of an acute burning and persistent—not spasmodic—character, extending gradually from the vicinity of the wound over the whole abdomen. This pain is greatly increased by pressure over the abdominal surface or by stretching out the lower limbs. The patient generally lies with the limbs drawn up and the thighs flexed on the pelvis to relieve tension. The features at first are flushed and have an anxious expression. The skin is hot and dry and the urinary secretion is diminished. The tongue is at first of white milky appearance, but soon becomes foul and loaded. The pulse varies from 98 to 120 beats per minute and has a hard, wiry feel. As the disease proceeds the abdomen becomes tense and tympanitic and vomiting supervenes, at first of a bilious character, but subsequently of dark-greenish watery fluid. When the disease progresses to a fatal termination the vomiting, or the attempt to vomit, becomes almost incessant. The features become sharp, the pulse increases in frequency but becomes weak and irregular, and the patient gradually sinks."

Heath's "Dictionary of Practical Surgery" gives the following: "Pain, tenderness, and the impairment of visceral muscular functions; alterations in the temperature,

[28] Dr. Meigs of Philadelphia in his book on the "Origin of Diseases" has thoroughly elaborated this view of the identity of the changes which are found in certain fibrous degenerations with those which are produced by old age. This work is solely on the anatomical side and is well illustrated by many drawings from his own specimens.

[1] Lectures on Surgery, vol. ii., p. 973.

pulse, and respiration; the temperature commonly elevated a few degrees at first, followed in later stages by depression; the pulse is characterised by greatly increased rapidity and hardness, which in the acute form is almost 'wiry' to the finger; the respiration is sometimes quickened and shallow. There are changes in the demeanour and facial expression. Lastly, there is the act of vomiting."

Jakob[2]: "Severe abdominal pain, vomiting, greatly distended abdomen, elevation of the diaphragm, tympanitic percussion note, or if exudation has taken place dulness in the dependent portions, Hippocratic facies, and, after several hours, heart failure."

Treves[3]: "Initial rigor. Intense, widely diffused, sudden pain, with shock, collapse, and vomiting. Pain may exhibit exacerbations. It is at first referred vaguely to the umbilicus but soon becomes general. The face shows exhaustion, pain, and terrible distress. The abdominal walls are at first sunken in and in some cases of perforative peritonitis this contraction of the belly-wall may be extreme. They then become rigid and board-like and the abdomen—except in corpulent subjects—is flat. There is very considerable tenderness to the touch, which depends mainly on hyperæsthesia of the skin. Later, as meteorism appears, the abdomen becomes ..... rounded and barrel-like. The extreme hardness of the muscular wall is less noticeable and towards the close of the case the parietes may become comparatively flaccid. Abdominal respiration ceases, the movements of the chest are exaggerated. The patient, in order to relax as much as possible the strain upon the abdominal muscles, lies with his knees drawn up and with his hands above his head. This attitude is very characteristic. Meteorism may be absent during the whole progress of the case. Constipation is usually marked, but the bowels may be loose. The temperature is liable to such extreme variation that no certain type of fever can be described. The pulse is at first small, sharp, hard, and wiry—averages 120 to 160 per minute; becoming softer and feebler towards the close. Respirations are increased."

Senn,[4] who distinguishes between plastic and suppurative peritonitis, gives as the symptoms of the latter: "Shock, variable temperature, normal, subnormal, or gradually reaching 104°. Vomiting and diarrhœa frequently conspicuous. May be persistent vomiting and absolute constipation. The symptoms may be mistaken for those of intestinal obstruction, and the abdomen has been opened with this idea." Henrot, quoted by him, has described a number of cases of perforation of the gall-bladder and the processus vermiformis where the symptoms pointed so strongly to the existence of intestinal obstruction that a wrong diagnosis was made by able clinicians. Physical signs and symptoms are sometimes utterly inadequate to distinguish between acute intestinal obstruction and diffuse peritonitis. In differentiating it must be remembered that in the absence of a tumour absolute constipation and fæcal vomiting are the most characteristic symptoms of obstruction, and that in peritonitis the pain is severe and continuous, with diffuse tenderness, tympanites, and absence of visible intestinal coils. "*In mechanical obstruction of the bowels the temperature is, as a rule, not above normal unless complications have set in, while in peritonitis a rise in temperature is the rule, although in some of the gravest cases it is subnormal.*" I have emphasised this sentence because it seems typical to me of most of the assistance to be found in these works—not that it is any worse than many to be found in English or German books of the same kind. The fact may be true enough, but this section is supposed to be written in order to clear up our difficulties, not to increase them; and for any help to be gained from it it might as well, and indeed far better, have been left out. I defy any man to make out from such a statement whether in any given case any reliance is to be placed on the temperature or not. The first half of the sentence would imply that such reliance is justified. In our supposititious case the temperature is not raised. It is below normal. Then it cannot be peritonitis—but the second half of the sentence shows that this is a mistake. It may, on the contrary, be one of the gravest and most dangerous cases. What can result but mental confusion from such statements? They may be as true as you please, but they are utterly irrelevant and irritating in a paragraph which is presumedly written for the illumination of those who consult it.

[2] Atlas of Clinical Diagnosis, p. 203.
[3] System of Surgery, vol. ii., p. 612.
[4] Principles of Surgery, p. 298.

Now, if you combine and analyse all these statements you will find that they may be reduced to the following list: sudden and continuous pain; tenderness; hot dry skin; temperature elevated, normal, or depressed; hard "wiry" pulse; quickened respiration; tympanites; clear note on percussion, unless effusion has occurred, when there is dulness in the flanks; distended abdomen; altered facial expression; flexed thighs and characteristic position of the body; and, later, vomiting.

Take these symptoms in detail. Is there one of them characteristic, except, perhaps, the expression of the face? Such an expression is known well enough to those who have had much experience of this condition, but can anyone describe it? Describe it, I mean, so that a novice will recognise it when he sees it for the first time? I have never seen such a description, and I do not believe it to be possible. It is called an expression of great anxiety; but it is much more than that. It is a combination of anxiety, pain, dread, and a piteous inarticulate appeal for help, but no one who has never seen it would recognise it merely from that description. Photographs might here be useful, but there is something so cold-blooded in attempting to photograph a patient in great pain and misery that few would submit to it unless morphia were first given, and then the characteristic expression would be lost or so modified as to render it useless for teaching purposes. Besides, these patients are so restless that any photograph would be spoilt in the process of taking.

Sudden and continuous pain in the abdomen is possible in too many things to be of any value. Besides, pain being a subjective sensation cannot be accurately gauged by anyone but the patient herself, and everyone knows that during the experience of great pain any statement made by the sufferer is not to be relied on for any scientific purpose. Then the capacity for endurance of pain, even the very sensation of pain, differs so widely in different people that no standard by which an outsider can estimate it is possible.

It is said, for instance, that the continuous character of the pain differentiates it from that felt in intussusception or impacted calculus where the pain is dependent upon the wave of peristalsis in the tube affected, but this is simply an academic distinction; true enough, doubtless, but utterly untrustworthy at the bedside. You must rely for the estimation of this upon the patient's own statements, and if she is at the moment suffering she will answer "Yes" or "No" indifferently, careless altogether of your academic distinctions and only anxious to hurry you into giving her something which shall relieve the torment. Moreover, peritonitis, as Treves points out, has its periods of exacerbation, due equally to peristaltic action, and he need be a very acute observer indeed who can feel certain in his own mind that during the intervals the patient is feeling no pain at all or is still suffering some. Besides, does a patient with impacted calculus or intussusception suffer no pain except when peristalsis is in action? The alternative conditions shade so easily into one another as to this symptom that it is practically valueless from a diagnostic point of view. There is pain, and intense pain: that is all that, in the majority of cases, can be said.

And if this is true of pain how much more of tenderness upon which some writers—Treves, for example—lay so much emphasis? A woman with pyosalpinx will be acutely tender over the iliac and inguinal regions, though there may be no peritonitis whatever present. Pressure over an inflamed gall-bladder will usually elicit this sign. A patient with cystitis may be distinctly tender on pressure over the hypogastrium, and yet there may be no peritonitis. The most tender abdominal wall is that in which there is cellulitis of the subcutaneous tissue, wholly unconnected with the peritoneum which itself is absolutely healthy. Who does not know the hysterical abdomen, with its abnormal—apparent—tenderness? And who can possibly say how much of what appears to be tenderness in any given case is not nervous shrinking from possible anticipated pain?

As to hot dry skin I confess it conveys no special meaning to my mind. In the first place I have seen peritonitis when the skin has been distinctly cold to touch, and the temperature, as marked by the thermometer, has been subnormal, whilst a hot dry skin is found in so many abdominal conditions that its value as a diagnostic sign is absolutely *nil*.

The pulse is described by many as hard and "wiry." Will anyone define what a "wiry" pulse is? This, indeed, seems to be one of those terms which have been copied from text-book to text-book without due consideration. It is a

term which conveys no definite idea and, as a matter of fact, the pulse in peritonitis is not always even hard; by which is meant, I suppose, incompressible. Suppose an impacted urinary calculus in the ureter, with coincident nephritis, but no peritonitis at all. Is not the pulse in this condition harder, more incompressible, more "wiry," if you will, than in any septic peritonitis?

Tympanites and distended abdomen are two symptoms which are certainly as often absent as present. I have seen, as many others have done, peritonitis with a distinctly scaphoid abdomen. When they do occur they do so in a comparatively late stage and suggest intestinal paralysis or obstruction, which may be the result of peritonitis or of a good many other causes. What abdomen can be more distended or more tympanitic than that of a case of sigmoid volvulus, for example, where there may not be a trace of peritonitis?

Vomiting, again, is not a symptom upon which any dependence can be placed. It may be due to irritant materials in the stomach or intestines, it may be due to foul smells, it may be due to many things besides peritonitis. When it becomes persistent it is too late to be of any service and even then is far more the consequence of intestinal paralysis, however produced, than of the peritonitis itself.

As to flexed extremities, if one was to trust to this alone we should diagnose peritonitis in all cases of simple colic, whether caused by lead or by improper and indigestible food, by the passage of gall-stones or of a ureteral calculus.

But it is often said you must not diagnose peritonitis by any one symptom, but by the combination of all. The same authorities, however, warn us that all may not be present, so that it is difficult to know in what cases we must depend on the first rule and in what we must depend on the presence of certain symptoms, and which. Such teaching is certain to leave the mind of the learner in a chaotic condition, with no feeling of certainty when in face of a definite case. And the fundamental reason is this, that whilst all these symptoms may or may not be present they are most of them not of the essence of the thing but represent possibilities in the case which may or may not occur.

Is it true, however, that we cannot depend upon any one symptom which when present is an absolute sign of this condition, and *vice versâ* the absence of which is an equally certain proof that peritonitis does not exist? a sign, moreover, which is objective and therefore does not depend for its security upon the loose statements of a patient half-maddened with pain. I believe that it is not true—that such a sign does exist easily demonstrable in all cases and capable of being estimated and estimated correctly by the observer himself. With acute peritonitis there is always rigidity of the abdominal muscles. Without peritonitis there is no rigidity. But it must be "rigidity." The surgeon who goes to his patient's bedside, flings down the coverings, and places a cold, possibly wet, hand suddenly on his patient's abdomen and relies on this sign will find all his patients suffering from this condition. But they are not. Such stiffening of the abdominal walls as he will meet with is not true rigidity, it is spasmodic contraction of the recti. The patient is not suffering from peritonitis, she is suffering from a totally different complaint, and its proper name is Dread of the Doctor. The physician who boasts of a list of from 60 to 100 patients every day is not to be trusted with this pathognomonic sign. He has no time to distinguish, and often, I fear, he has not the patience. Patience and time are essential. The hand must not be suddenly applied, nor should it be used in the standing position. The surgeon must find time to sit down. His hand must be warm, warmer, if possible, than the patient's skin. The tips of the fingers are not to be used. The entire hand should come in contact with the abdomen like a feather, so that it is almost impossible for the patient to say when actual contact is made. It should then lie without any weight almost entirely supported by the surgeon's own muscles for a few moments motionless, then gradually and gently move with an imperceptible sliding action over the surface. Thus, and thus only, will he be qualified to say whether or not there is actual muscular rigidity.

Can we demonstrate the truth of this? I think we can. Analogically, the abdomen is a large joint. To create a joint bone and cartilage are not necessary. A joint is primarily a normal solution of continuity between structures permitting of their movement the one upon the other. Such movement is produced by the action of muscular fibre. Between the structures is a membrane which secretes sufficient fluid to enable this movement to be easy, smooth, and painless. There is a telegraphic, automatic communication by means of a nerve arc with nerve centre, afferent and efferent nerve fibres, connecting the interior of the joint with the muscles which move that joint. Hilton long ago demonstrated this with reference to the bony joints of the body, and Thomas based his method of treatment—now of world-wide acceptance—upon this fact. Any inflammation of the lining membrane produces such irritation of the intra-articular afferent nerves as to be at once and automatically referred to the nerve centre in the spinal cord whence it is as instantaneously conveyed to the muscles moving that joint, and produces in them a tonic contraction, nature's own admirable method of securing rest to the parts affected; and this is precisely what occurs, and must occur in this, the largest joint of all. The rigidity is not confined to the abdominal muscles, though its occurrence in them is perhaps the more easily noted. But it is the cause of the flexed thighs which have been pointed out by so many observers as a separate and distinct sign, but which is now seen to be correlated with the abdominal contraction and explainable by the same law; the psoas and iliacus muscles are part of the muscular coating of the abdominal cavity, influenced by the same nerves and forced to contract in the same way, and show their sympathetic contraction by the flexed drawn-up thighs. It is probable, too, that some of the difficulty experienced in obtaining fæcal evacuations in peritonitis is due to a rigid condition of the levator ani which also forms part of the muscular covering of the peritoneum. Many of the symptoms noted are thus seen to depend upon a common cause—a cause which is inherently present in all cases from the very nature of the condition.

The operation of this law may, indeed, be traced in other "visceral joints," as Kelynack terms them. In acute pleurisy where the "synovial" membrane, the pleura, is affected is not one of the earliest and most characteristic signs the fixation of that side of the chest in which the pleurisy is situate? In inflammation of the tunica vaginalis is there not tonic contraction of the cremaster and dartos muscles, so markedly different from simple hydrocele, which is not dependent on any process of inflammation at all, but is due simply to a loss of the normal balance between secretion and absorption. In cerebral meningitis we have the rigid neck so characteristic of that affection, and in infective spinal meningitis the rigid erector spinæ, but however that may be, and whatever importance may be attached or not to such additional illustrations of Hilton's law, it is indubitable that in the case of the peritoneum it furnishes us with a clear, concise, and scientific criterion upon which we may safely base our diagnosis, a symptom which we can all appreciate, and which will put an end to the miserable indecision from which we have all suffered—no one, perhaps, more than the present writer.

Are cases required to illustrate this dictum? Here are three, each in its way, I think, instructive. In March of this year I operated upon a man who suffered from intussusception of the sigmoid flexure into the rectum. 14 days after a preliminary colotomy I performed Maunsell's operation through a median abdominal incision. Two days later I received an urgent message from my house surgeon to the effect that peritonitis had developed. It was very possible. In such an operation, as is well known, the interior of the intestine is exposed, and the fingers and instruments of the operator, after touching the mucous surface in removing the intussusceptum, are applied again to the peritoneal surface whilst closing the longitudinal incision in the intussuscipiens. No one under such circumstances can feel sure that he has performed an aseptic operation. When I saw the patient he had been vomiting, he was complaining of pain, and his pulse was thin, rapid, and weak. The temperature was 101° F. and his general appearance was decidedly bad. He was lying low in bed, and altogether, if one was to rely on the symptoms usually detailed in text-books, my house surgeon was fully justified in his diagnosis. But the abdominal wall was everywhere supple and with perfect confidence I put peritonitis altogether on one side. The result justified my opinion. A hypodermic injection of strychnine, repeated in four hours, together with stimulants and some stomachics, put a totally new aspect on affairs, and everything went well. The patient recovered and nothing more was heard of peritonitis.

The second case was even more critical. A woman, aged 23 years, came into hospital with the largest double pyosalpinx I have yet seen. The mass extended to the level of the umbilicus, her temperature was 103° F., her legs were drawn up, and she was in very severe pain. During removal of the greatly enlarged tube of the left side some thickened omentum which had plugged the fimbriated extremity tore away, allowing the escape of some thin, ichorous pus. The majority of this was caught on sponges, but one could not be by any means sure that some had not escaped and soiled the peritoneum. The abdomen was dried out and closed without drainage. She suffered from bronchitis and for some days was extremely ill. The temperature went up again on the fifth day to 103° F. The pulse was 116 and the respirations were 36. But the abdomen remained supple throughout. A month later she developed a subdiaphragmatic abscess which was opened and washed out. At length the patient perfectly recovered. Now, although this pus was virulent enough to produce cellulitis behind the peritoneum, ending in abscess, peritonitis was never present. This case proves perhaps still more forcibly the power of the peritoneum to dispose of micro-organisms under prompt purgation with calomel, but it demonstrates also the value of this sign (muscular rigidity), absence of which was throughout depended upon and proved reliable.

The third case, ending in death as it did, enabled us to prove by post-mortem examination the truth of my contention. It has not been the only one, but is, I think, sufficient.

During the last few years I have been investigating as to the possibility of sealing all abdominal wounds with celloidin, so as to avoid the use of dressings, bandages, &c., and I published in April of last year in the *Medical Chronicle* several cases illustrating this practice. One of my earliest cases was fatal. A large subcutaneous hæmatoma formed, owing no doubt to defective hæmostasis, and deceived by the absence of swelling and redness, which is one of the results of this method, I did not diagnose it. The skin was, as might be expected, extremely tender; the patient's temperature rose to 102° and she died five days afterwards, with all the symptoms so common in septic peritonitis, from septic intoxication, but the abdominal wall, tender as it was, was always supple. Post-mortem a large accumulation of broken-down offensive blood and pus was found in the subcutaneous and submuscular tissues. The peritoneum beneath, however, was absolutely closed and free from all signs of inflammation. There were no adhesions, no redness; all was absolutely smooth and unchanged. The intestinal coverings were absolutely normal. No case has to my mind, although I have seen many, so absolutely proved the value of muscular rigidity in determining the presence or absence of acute peritonitis.

The presence or absence of acute peritonitis can, therefore, in all cases be gauged with absolute certainty by the presence or absence of this one essential sign. Inasmuch as this rigidity is temporary, lasting about three or four days, it is useless as a pathognomonic sign in cases of chronic peritonitis, which differs from acute in course, causes, importance, and treatment. But in acute peritonitis it is always necessarily present, and that during the time in which a diagnosis has to be made if it is to be of any value at all.

Manchester.

SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.—The eleventh annual meeting of the Bristol branch of this society was held on May 29th, under the presidency of the high sheriff. The report stated that 428 complaints were attended to during 1899 and these affected the welfare of 967 children and involved 570 offenders. The financial statement showed that the total local expenditure amounted to £560 and there was a favourable balance of £3 remaining.

VACCINATION LAW.—At the meeting of the Frome (Somerset) Board of Guardians held on May 30th the vaccination officer for the Nunney sub-district reported the result of a prosecution at the magistrates' court on May 24th, when one of the arguments of the defending barrister was that there was no evidence of any kind to show that the notice which the public vaccinator had sent by halfpenny post had reached the person to whom it was intended. The public vaccinator for the Nunney district was therefore requested to send the notice in future by registered post, the cost of which would be defrayed by the guardians.

THE INFLUENCE OF THE BUXTON THERMAL WATER ON THE EXCRETION OF URIC ACID.

BY WILLIAM ARMSTRONG, M.R.C.S. ENG.

THE Goulstonian Lectures of 1897,[1] in which Dr. Luff so ably dealt with "The Chemistry and Pathology of Gout," marked a distinct advance in the treatment of that disease. It was shown that in the Gowland-Hopkins method there was at command a test which, while it showed the exact amount of uric acid passed, did not throw down the xanthins and hyper-xanthins—the great blot on certain other methods in general use; the necessity for the purpose of exact observation of testing a sample of the mixed urine of the 24 hours was pointed out; and more than all it was clearly demonstrated that the gouty patient, so far from passing uric acid in excess, in the great majority of instances passed too little; that there was a daily storage going on which, although small in amount, was still sufficient to keep up certain morbid conditions; or if it had no such gradual outlet eventually culminated in an acute attack of articular gout. In repeating these experiments I observed that in patients drinking or bathing in the Buxton thermal water there was a constant and in some cases a considerable increase in the quantity of uric acid excreted, and that this action was the more marked as the natural temperature (82° F.) was approached. Neither the mineral constituents nor the temperature of the water accounted for the facts observed, while nitrogen gas, although present in very large quantity, had always been looked upon as a simple element which was therapeutically inert. It seemed rather significant, however, that Wildbad, Gastein, and Buxton—all associated with relief to the gouty—possessed nothing in common, both temperature and mineral constituents differing, except the presence of nitrogen, and it could not be overlooked that the recent researches of Lord Rayleigh and Professor Ramsey had shown that gas to be not an element but really a very complex body, the whole chemistry of which is probably not yet known.

With a view to finding, if possible, the *rationale* of the "gout cure" for which the Buxton thermal water had so long been noted, a large number of observations and many control and cross-experiments have been made. Over 300 persons have contributed to this investigation. They were of various ages; all except ten suffered from gout in one form or another; these ten were persons in normal health, showing no signs of the gouty diathesis. Their ordinary mixed dietary was not altered in any way. Some of the patients only drank the thermal water, 24 ounces being taken daily, divided into three doses; some bathed only; while a third section both drank and bathed. In all cases the 24 hours' urine was tested, and the first two examinations were made before either the bathing or drinking "cures" were commenced.

The Buxton thermal water is discharged from the earth at a temperature of 82° F. It is soft, clear, and of a light bluish colour, almost free from taste, and without odour. Several exhaustive analyses have been made, the most complete by Dr. Thresh, who devoted much time and care to the investigation. His results were as follows. Calculated into grains per gallon the water was estimated to contain: bicarbonate of calcium, 14·01; bicarbonate of magnesium, 6·02; bicarbonate of iron, 0·03; bicarbonate of manganese, 0·03; sulphate of barium, 0·05; sulphate of calcium, 0·26; sulphate of potassium, 0·62; sulphate of sodium, 0·84; nitrate of sodium, 0·03; chloride of calcium, 0·02; chloride of sodium, 3 10; chloride of ammonium, trace; chloride of magnesium, 0·95; silicic acid, 0 95; organic matter, 0·02; carbon dioxide, 0·20; nitrogen, 0·19; total, 27 32. Lithium, strontium, lead, and phosphoric acid, traces. There were six cubic inches of nitrogen gas to the gallon and a small quantity of carbonic acid gas. This nitrogen has been carefully tested and contains 2 per cent. of argon and a trace of helion. It will be seen that the mineral constituents are small in quantity and of slight therapeutic power and that

[1] THE LANCET, March 27th and April 3rd and 17th, 1897.

there is a large quantity of nitrogen gas, a little in suspension, but by far the greater quantity in solution.

The following lines were laid down for the purpose of this investigation: (1) to note the effect of drinking the thermal water as it emerged from the spring; (2) to eliminate (*a*) by cooling and (*b*) by heating, the contained gases and to note the comparative effects; (3) to test the relative effects of drinking ordinary water at the same temperature; and (4) to note the effects of bathing in the thermal waters at 82° F., 90° F., 96° F., 100° F., and in the ordinary water at 82° F. and at 100° F. The average quantity of urine for the 24 hours before treatment commenced was a little under 46 ounces in the non-gouty and about 41 ounces in the gouty; in the former the uric acid averaged 0·780 grammes per day and in the latter 0·660 grammes.

Drinking (over 60 cases).—1. Thermal water drunk at the spring at 82° F. Average urine after one week, 57 ounces; uric acid, 0·799 gramme. 2. Thermal water allowed to cool to 70° F. Average urine, 45 ounces; uric acid, 0·700 gramme. 3. Thermal water heated in closed vessel to 110° F. Average urine, 48 ounces; uric acid, 0·696 gramme. 4. Ordinary drinking water at 110° F. Average urine, 47 ounces; uric acid, 0·696 gramme.

Bathing (over 100 cases).—1. At 82° F. Average urine, 55 ounces; uric acid, 0·939 gramme. 2. At 90° F. Average urine, 50 ounces; uric acid, 0·874 gramme. 3. At 96° F. Average urine, 47 ounces; uric acid, 0·777 gramme. 4. At 100° F. Average urine, 40 ounces; uric acid, 0·680 gramme. 5. Bath in ordinary water at 82° F. Average urine, 41 ounces; uric acid, 0·675 gramme. 6. Bath in ordinary water at 100° F. Average urine, 38 ounces; uric acid, 0·669 gramme.

Drinking and bathing at 82° F. (over 100 cases).—Average urine, 60 ounces; uric acid, 1·004 grammes.

While drinking the water the quantity of uric acid excreted gradually reached its maximum in from 14 to 20 days, kept about this figure for another seven or eight days, and then gradually declined to the normal amount. This was also the rule when bathing in the water heated to 90° F. and over; but *immersion* alone in the water at its natural temperature (82° F.) was often followed by a considerable increase in uric acid excretion from the very first bath. It will be noted that this bath contains the full amount of nitrogen gas undisturbed by heating.

The results of this investigation may be summed up as follows: (1) that the excretion of uric acid and the flow of urine are both largely increased by the drinking of, and by immersion in, the Buxton thermal water; (2) that it is more efficacious when bathed in than when drunk as regards uric acid excretion; (3) that the diuresis is somewhat greater when drunk than when used as a bath; (4) that any deviation from the normal temperature either by heating or cooling interferes with its efficacy; and (5) that while the alterations in temperature would not be likely to diminish the therapeutic properties of the salts they would, on the other hand, greatly interfere with the contained gas.

The late Dr. Robertson, so long the leader of the medical profession in Buxton, who did so much to press forward its claims as a gout spa, wrote: "It may be advanced that the modern researches of chemistry have caused more and more importance to be attached to the great elementary principle with which the Buxton tepid waters are surcharged. The very large proportion of nitrogen contained in the essential crystallisable principles of tea, coffee, and cocoa, in taurine, the great azotised constituent of the bile, in the various fibres and tissues, in the secretions and excretions of the body, the consumption of nitrogen shown to be involved in every movement and process of the animal systems, are so many indications of the inference deducible from the great advance of modern chemistry, and so many reasons why this nitrogen in an available form for internal and external use may have a significance which may hardly admit of exaggeration. Argon being much more soluble than nitrogen and therefore more rapidly absorbed through the skin and mucous membranes appears to give an additional explanation of the influence on the tissues of the body of these nitrogenous waters."

Dr. Thresh writes: "Doubtless much of the gas is liberated within the very pores of the skin itself during bathing and acts in what may be considered its seminascent state, producing effects altogether unattainable by the use of the same agent in any other condition."

It is also interesting to note some recent work regarding the chief mineral constituent of the Buxton thermal water, calcium bicarbonate. Kionka of Breslau gave powdered eggshells to birds and by this means increased the excretion of uric acid from 40 to 50 per cent. Van Noorden has recommended the use of lime in this form as a remedy for gout. It is not impossible therefore that in the combined action of the nitrogen gas and of the lime salts may be found the explanation of the undoubted influence of the Buxton thermal waters on uric acid excretion. If it be true, as seems to have been proved beyond doubt, that the manifestations of gout are largely due to deficient excretion of uric acid, it is of importance that a natural water which so largely increases that elimination should have its therapeutic position placed upon a definite scientific basis.

Buxton.

ON SUPRAPUBIC LITHOTOMY IN OLD MEN WITH ENLARGED PROSTATE.[1]

BY W. THELWALL THOMAS, F.R.C.S. ENG.,
HONORARY ASSISTANT SURGEON, ROYAL INFIRMARY, LIVERPOOL; ASSISTANT LECTURER ON SURGERY, UNIVERSITY COLLEGE, LIVERPOOL.

WE have but to look through any pathological museum to realise how irregularly an enlarged prostate disports itself and to notice a well-marked pouch behind the middle lobe in a great number of the specimens. The capacity of this pouch during life is readily ascertained by measuring the quantity of so-called "residual urine" that can be drawn off, quantities of two, four, or even more ounces being met with. Gravel in small fragments or well-formed calculi coming down the ureters emerge into this pouch and there lie, unable to surmount the barrier offered by the middle lobe of the prostate to escape per urethram; they may remain there unsuspected for months without causing symptoms. Cystitis with decomposition of the urine does not always follow; in two of my cases the calculi were numerous, uric acid in composition, and the urine was acid. The symptoms under these conditions are so slightly different from those of enlargement of the prostate that the existence of stone is sometimes overlooked. Slightly increased frequency of micturition and occasional pain may attract attention; in one case a little blood was noticed in the urine on one occasion. Should catheter life be entered upon then cystitis often complicates the case, septic in character in most cases from want of due precautions; the urine becomes ammoniacal and purulent, severe pain is often present, blood is more frequently passed, and the calculus becomes encrusted with rough phosphates. When in a case of enlarged prostate with any degree of residual urine symptoms become in any way exaggerated it is well as a routine practice to sound for stone and if the prostate be very large to use a special sound (Kane's) or cystoscope to explore the pouch behind the middle lobe. An ordinary bladder-sound will occasionally fail to discover a stone in this pouch and aspiration sounding is not always to be relied upon. It is hardly necessary to emphasise the importance of a thorough cleansing of the urethra and the sterilising of the sound before use; the bladder in these cases is particularly liable to be infected, and if it becomes so it adds greatly to the gravity of the condition. Having ascertained the presence of a stone, how best to deal with it becomes the question. Given an old man with an enlarged prostate, the stone in a pouch behind it, a congested, friable, possibly ulcerated mucous membrane, maybe some degree of septic cystitis, and the bladder-wall containing numerous small pouches bounded by prominent fasciculi—is the operation to be lithotrity or lithotomy?

The objections to crushing in these cases are: (1) the difficulty, or even the impossibility, of seizing the calculus; (2) if caught and broken, then the difficulty in finding the fragments; and (3) granted the possibility of crushing, then, aspiration diffusing the fragments into the innumerable pits in the mucous membrane, the great uncertainty of washing out all the pieces, for in these cases the patient cannot be trusted to pass any portions left behind, they will lodge behind the prostatic enlargement and form nuclei for fresh calculi.

[1] A paper read at the Liverpool Medical Institution on March 8th, 1900.

The difficulty of seizing a calculus behind an enlarged middle lobe with a lithotrite will be readily understood on examining museum specimens. In the first case to be mentioned, after luckily finding the stone with an ordinary sound before placing the patient under an anæsthetic, we utterly failed to find it afterwards with sound or lithotrite, although the patient was rolled about on the operation table and the base of the bladder manipulated through the rectum. That fragments are left behind after lithotrity seems very likely when we read of cases crushed many times (five, six, nine, and ten times). Over 20 per cent. of cases in a recent table published by a skilled lithotritist required subsequent crushings. Perineal lithotomy is not applicable owing to great increase in the depth of the perineum, to such an extent in some cases that neither finger nor forceps can reach the stone. The suprapubic operation carried out with modern precautions is simple and almost bloodless; it enables the bladder to be thoroughly explored and allows of the extraction of the calculus and of treatment of the enlarged lobe if thought advisable. It becomes the proceeding of choice in the cases under consideration. Further, the bladder can be sutured and the wound be treated antiseptically.

Before resorting to the operation it is advisable to render the urine and urinary tract as sterile as possible. If cystitis with ammoniacal urine be present, the administration of urotropine in five-grain doses thrice daily and washing out the bladder with chinosol lotion (1 in 1200) twice a day, or oftener, have answered best in my experience. Boric acid is much too feeble an antiseptic if the urine be "high." Chinosol is non-poisonous and a powerful antiseptic. It is imperative that every aseptic and antiseptic precaution should be taken in urethral and bladder surgery; to do so means absence of rigors and complications. There is an idea far too prevalent that any catheter from an old drawer or hand-bag smeared with that abomination—carbolic oil—will do. The catheter should be boiled or steamed, the glans penis should be thoroughly cleansed with chinosol lotion, and the urethra should be washed out with the same. The lubricant used is a mixture of soft soap, glycerine, and water in the proportions of eight, six, and four. Four grains of potassium mercuric iodide dissolved in four ounces of water before mixing makes a proportion of nearly 1 in 2000.[2] In ordinary cases, without ammoniacal urine, the administration of urotropine is enough. It is useful in all bladder, urethra, and kidney cases that require surgical treatment to administer urotropine internally for a few days before operation—that is, of course, if the condition does not urgently demand operative proceedings.

Operation.—The pubic hair having been shaved and the skin prepared for an aseptic operation, a purgative is administered on the day before, and the rectum is washed out on the morning of, the day of operation. The patient having been anæsthetised, a catheter is passed to empty the bladder and to allow of washing out if necessary. An inflator, ball syringe, or, better still, a small bicycle pump, is attached to the catheter. An incision, three or four inches long, is made in the middle line of the abdomen above and extending on to the pubes, the cut is deepened until the extra-peritoneal fat is exposed immediately above the pubes, retractors now keep the sides apart, one rectus being nicked if enough room is not obtained. Air is pumped into the bladder until the viscus rises into the wound like a balloon; the peritoneal reflexion is seen moving upwards. A couple of silk loops are passed through the muscular coat of the bladder by means of a handled needle; these serve as fixation points and are held by an assistant to keep the bladder well up in the wound after opening. A small incision is made in the bladder and the air escapes. The catheter is withdrawn and the finger is passed in to locate the calculus and to ascertain its size. If small, the stone can be readily extracted by Tait's gall-stone forceps, which takes up less room than the unnecessarily clumsy lithotomy forceps; if large, the wound in the bladder is extended, the mucous membrane being divided to a lesser extent than the muscular coat, blunt hooks are inserted above and below to keep the opening on the stretch, and a pair of lithotomy forceps is used to seize the calculus. After the calculi have been removed the bladder is thoroughly examined with the finger and an inspection is made of the interior, aided by light from a forehead electric lamp. The bladder wound is sutured, continuous chromic gut for the mucous membrane and continuous silk *à la* Lembert for the muscular coat being employed. The bladder suture is now tested by air distension, and if secure a few ounces of chinosol lotion are used to wash out any small blood-clot that may be in the bladder. The silk loops are removed and a small incision is made through the skin to one side of the middle line to accommodate a small glass drainage-tube passed down to the neighbourhood of the sutures in the bladder-wall. The original skin incision is closed by sutures and a gauze dressing under a double spica bandage is applied. The catheter is left in the bladder, tied in position, and by means of a rubber tube attached to it it conducts urine into a vessel containing lotion for a few days. The bladder is washed out with a few ounces of chinosol lotion daily. Four cases in old men have been operated upon, the above description in all its details being, however, only applicable to the last two. The patients' ages were 61, 63, 70, and 80 years, they all recovered without complications, and they have remained free from calculi. The following are the cases.

CASE 1.—The patient was a man aged 61 years. On August 22nd, 1897, he had severe renal colic, right-sided, which lasted 48 hours in all; the urine was thick and he had great pain in the penis when passing urine. He had been troubled with frequency of micturition for months, but had never required catheterising. On August 24th, when he came under observation, the urine was faintly acid, of specific gravity 1022, and contained blood but no pus. The bladder had two ounces of residual urine. The ordinary sound revealed a calculus. On the 27th before administering an anæsthetic the stone was sounded under chloroform. On asking the dressers to "feel" the stone the sound could not strike it, and although we rolled the patient about and had the base of the bladder manipulated from the rectum neither sound nor lithotrite could find the stone. Lithotrity was thus clearly out of the question. Suprapubic lithotomy was performed, boric lotion was used to distend the bladder, and the stone was found in a deep pouch behind the middle lobe of the prostate. No ordinary lithotrite could possibly have grasped it. On the sixth day the catheter was withdrawn and on the ninth day the glass drainage-tube was removed. Two days later he developed an attack of bronchitis, which delayed his convalescence, but his bladder remained all right, but on two occasions we washed the bladder out as a precaution. The calculus removed weighed 46 grains and consisted of uric acid coated with phosphates. In January, 1900, it was ascertained that he had had occasional turbid urine since the operation, but washing out with chinosol lotion put that right. The bladder was examined with no evidence of calculus.

CASE 2.—A man, aged 70 years, was seen in consultation with Mr. J. F. Ronayne of Liverpool on June 26th, 1897. For the last six months the patient had been troubled by greatly increased frequency of micturition, and latterly dribbling of ammoniacal urine; he had occasional severe spasms of pain on micturition and some blood had passed. He had a very large prostate as felt through the rectum. On passing a sound a calculus was found at the bladder orifice of the urethra; the passage of the sound pushed it into the bladder, and it became lost in a pouch behind the enlarged prostate. On June 29th suprapubic lithotomy was performed. The catheter was removed in 48 hours on account of the urine passing alongside it. A glass drainage-tube was removed in 72 hours. On the fourth day a little urine escaped through the sinus left by the drainage-tube; this was not repeated and on the eleventh day the patient was up and about. The calculus weighed 120 grains and consisted of uric acid covered with rough phosphates. On June 23rd, 1899, there was some cystitis, the urine was acid, and there was ropy mucus. There was no calculus. The bladder was washed out.

CASE 3.—The patient was a man, aged 63 years, under the care of Dr. W. McGeagh of Liverpool. He was seen on Feb. 17th, 1899. For two years he had had greatly increased frequency of micturition and blood was noticed in the urine once. Lately he had suffered from severe pain in the perineum. The prostate was much enlarged. There were two ounces of residual urine. The bladder was examined by the cystoscope; a collection of reddish-brown calculi was seen in a pouch behind the prostate. On the 20th suprapubic lithotomy was performed; at the operation Dr. R. T. McGeagh and Dr. W. McGeagh assisted. Air distension was used. 15 calculi, uric acid in composition and weighing 140 grains, were removed. The catheter was removed daily, cleansed, and re-introduced. The catheter and drainage-tube

[2] Messrs. Clay and Abraham, chemists, Liverpool, put up this lubricant soap in collapsable tubes.

were removed on the third day. On the fourth day the patient was much troubled by flatus, the abdomen became distended, and he vomited. A turpentine enema was administered which caused a free evacuation and he was soon well. On the tenth day he got up. In February, 1900, he was well and strong, doing heavy farm work.

CASE 4.—The patient was a man, aged 80 years, under the care of Mr. J. Herbert Sykes of Birkdale. He was seen on March 2nd, 1899. 15 months previously he had passed some gravel. He had experienced extreme irritability of the bladder since. Hurrying caused pain. The urine was acid and contained blood. Cystoscopic examination revealed several calculi behind the middle lobe of the prostate. On March 16th suprapubic lithotomy was performed, Mr. Sykes assisting. Air distension was used. Six calculi were removed; they were uric acid in composition and weighed 133 grains. The catheter was removed on the sixth day and the glass tube on the eighth. The patient got up in three weeks. He had no complications, but he was feeble and the weather was cold, so he was kept in bed longer than were the other patients. On March 3rd, 1900, the patient was keeping very well. He had some tenderness over the operation scar but no pain. He passed urine every two hours and occasionally uric acid dust.

Liverpool.

MONOGAMY IN ITS RELATION TO LONGEVITY AND THE DISEASES OF LATE LIFE.

BY HARRY CAMPBELL, M.D., B.S., F.R.C.P. LOND.,
PHYSICIAN TO THE NORTH WEST LONDON HOSPITAL AND TO THE WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM.

THE increase in the death-rate from cancer has of late attracted, and rightly attracted, the attention of medical men, and various opinions have been advanced to account for it. One reason doubtless is that owing to the increased average length of life more people live into the cancerous age now than formerly. Some hold this to be the entire explanation and doubt if there has been any increase in the individual tendency to the disease. I believe, however, that I can see one reason why the individual tendency should increase, and though the suggestion I have to offer may at first sight appear chimerical I yet hope to advance a convincing argument in its support. My contention is that monogamy tends to favour the increase in our race of all late-life diseases, cancer among others, and to shorten the vital span.

Intent on his microscope and test-tubes the pathologist is all too prone to overlook first principles. I have long wondered at his indifference to some of the grand truths of biology—at his failure to realise, for instance, that in order to maintain a high standard of racial efficiency there must be a ceaseless and rigorous elimination of the unfit. The belief that we can rear a healthy race by a perfect system of sanitation, and by that alone, is one of the most grievous fallacies of our time. Sanitation is doing much, and will do more, but it will never by itself secure a supremely healthy race. This end can only be attained by a vigilant weeding-out of the unfit. We are seeking, but shall ever seek in vain, to elude the inexorable law.

No species is, or ever can be, stereotyped. No two organisms are born exactly alike. Taking all the children of a family, and striking their mean standard of fitness, we find that some surpass, while others fall short of, this standard, and it is quite impossible to prevent racial deterioration unless those who fall *far* short are eliminated. I here refer to general fitness, but my proposition applies to each and every character of the individual. To take an example. A high *racial* (I use this term as distinguished from *individual*) excellence in respect of visual accommodation can only be maintained by a stringent elimination of those displaying errors of refraction. In civilised communities such are not eliminated, and consequently the race is deteriorating in respect of eyesight. In this instance the defect is remediable and the loss is in the main an æsthetic one, but countless other instances could be mentioned in which defective elimination is lowering the efficiency of our race, and in consequence we have among us a vast multitude of the unfit. As a physician I am seeing every day of my life people whom I am compelled to class among nature's failures—people who fall short of the standard which makes life worth living, people who in virtue of their unfitness suffer more than they enjoy. When, therefore, I see, and share in, the vain struggle to patch up such failures and when I read elaborate systems on treatment I ask myself: Why not look facts sternly in the face and strike at the root of the evil by conforming to the supreme and inexorable law? I am convinced that some day this will be done, and that the wilful begetting of inefficient humans will be looked upon as scarcely less serious than the destruction of those already launched into being.

I make these observations because it is needful for my argument to insist upon the importance of this factor of elimination in keeping down the tendency to disease. In my work on "The Causation of Disease" I lay it down as an axiom that all non-accidental deaths occurring before the end of reproductive life are, racially considered, deaths of the unfit, such deaths acting beneficially on the race by limiting the production of unfit offspring. If the unfit individual dies before the procreative period he can leave no offspring whatever to inherit his unfitness; if he dies during this period he has an opportunity, increasing with every year of survival, of leaving unfit offspring; while if he dies after the procreative period he has had the opportunity of leaving his full complement of such offspring. Hence so far as the racial effect of death from unfitness is concerned, it is greatest when it occurs before the reproductive period, becomes less and less as it occurs later and later in this period, and ceases altogether when it takes place after it. The purifying action of elimination varying thus at different ages, we find the tendency to grave disorder is least before procreative life, steadily increases during it, and rises enormously at its termination. Inasmuch as post-procreative life comes not at all under the corrective influence of elimination I should expect to find the organism manifesting many defects directly this period is entered upon. I should, indeed, be prepared to find, not only an enormous increase in the tendency to disease at this time, but *a tendency for all organisms, vegetable as well as animal, to die soon after* the cessation of reproductive life. How far this conclusion is borne out by observation I know not, but I believe it is true of man.

This line of thought renders it important to determine the average limit of the procreative period in man. The most vigorous specimens of the human male certainly retain procreative power beyond the allotted age of the Psalmist; and we owe it, I believe, to this very circumstance that many of us are able to reach or even live beyond this limit. Had no man during the last 100,000 years got offspring after the age of 50, we should all probably tend to die of old age about this time. There has, however, been no such limit to reproduction. In primitive communities, e.g., the man who by his great physical superiority becomes the warrior-chief or king may continue to get children until well on in years, and may thus leave many more children than the average man. Now children thus got, female as well as male, tend by the law of heredity to live as long as their father, to resist deadly disease as long as he. It is true that children got by fathers who procreate into old age must have always formed a small proportion of the total number of children born. Nevertheless, they have, I contend, exercised a leavening influence on the race, an influence which has been at work from the time of the ape-like man. The ability to live into the sixties and seventies, or even longer, we owe to the vigorous man of fine physique who retains his procreative power into advanced life. The woman, on the other hand, has played no part in the evolution of this power: her ability to live beyond 40 or 45 has no racial influence, since it does not increase her opportunity of leaving offspring to inherit it.

Now in civilised communities the tendency, observed in the more primitive ones, for the man who lives to a vigorous old age to leave more children than the average man is not great. The majority of men among the civilised have children by one wife only, and she is generally about the same age as the husband. The effect of this is to reduce the age-limit of reproduction in the man to that of the woman. A man, therefore, marrying a woman about his own age, and possessing the power of propagation into advanced life, leaves no more children to inherit his superior death-resisting powers than the inferior man who dies at 45. Monogamy in such a case reduces the superior man to the reproductive level of the inferior man, and robs the race of a number of

individuals whose birth would diminish the racial tendency to disease in the later years and increase the racial span of life. The effect of monogamy, in fact, is to increase the racial tendency to disease after middle life and to shorten the vital span.

Among the diseases one would expect to be increased by the monogamous limitation of procreative life is carcinoma. Reckoning for the sake of argument 40 years (which is, indeed, below the mark) as the average age-limit to procreation among monogamous people, we must regard carcinoma as essentially a disease of post-procreative life and one on which elimination has little or no racial effect. Before the individual with a tendency to this disease develops it he has had abundant opportunity of leaving children to inherit the morbid tendency. Nothing hinders his contribution to the species being as great as that of the individual possessing the minimum tendency to malignant disease. Thus monogamy tends to increase the percentage of cancerously disposed individuals.

While, however, monogamy is thus exercising an injurious influence on our race, polygamy is a sociological impossibility, and happily we have at our disposal a much more efficacious means than is afforded by it of securing to the fittest the largest number of offspring—of giving full play to that searching process of elimination which alone can sustain a high level of racial fitness. Nature's method of elimination is a merciless one; she unceremoniously sacrifices the individual for the benefit of the race—so careful of the type is she, so careless of the single life. The sole object of individual elimination, racially considered, is to prevent the unfit individual from leaving offspring to inherit his unfitness, and Nature in her rough-and-ready way achieves this object by simply wiping him out of existence. The same end can be attained, however, by the unfit abstaining from getting unfit offspring and choosing to join the ever-increasing army of the non-marrying. Elimination from the racial standpoint means not having offspring, and all who do not leave offspring are racially eliminated—unrepresented in posterity.

The best way, therefore—indeed, the only way—effectually to raise the racial standard is for the unfit to submit to voluntary elimination and to abstain from getting unfit variations. Not only would it be possible in this way to diminish the tendency to cancer and a host of other fell diseases, but it would also be possible, though some may think it undesirable, to extend the span of life almost indefinitely. I have elsewhere shown that a man does not grow old, as is so often assumed, by wearing out, like his boots. If such were the case he would begin to wear out from the very beginning of his existence, whereas it is precisely in the years of developmental life when most energy is expended that there is least evidence of wearing out, the organism, on the contrary, steadily advancing in efficiency. The period of senility is as much a part of the physiological vital cycle as that of development itself.

I would observe, in conclusion, that I do not advocate any startling measures of reform. The change I have hinted at can only come gradually, but come it must, and who fitter than ourselves to help on the consummation?

Wimpole-street, W.

UNIVERSITY OF CAMBRIDGE.—The Examiners for the Final M.B. Examinations have been appointed as follows:—Medicine: Dr. D. B. Lees, Dr. Isambard Owen, Dr. D. MacAlister, and Professor Greenfield. Surgery: Professor Chiene, Professor E. Ward, Mr. Bernard Pitts, and Mr. Golding-Bird.—The Regius Professor of Physic and Dr. W. Collingridge, medical officer of the Port of London, are to represent the University at the Paris Congress of Hygiene and Demography in August.—A course of laboratory work in chemistry, &c., for the D.P.H. examination will be given by Mr. J. E. Purvis at the Chemical Laboratory during the ensuing long vacation. The course will be open to practitioners who are not members of the University and it will begin on July 6th.—The Vice-Chancellor, Mr. Chawner, has been elected to hold office for another year.—Mr. Wilberforce of Trinity College has been appointed Lecturer on Experimental Physics in the place of Mr. W. N. Shaw, F.R.S.—The plans for the medical school buildings having been approved by the Senate it is proposed during the summer to obtain specifications and tenders for the erection of the first portion facing Downing-street.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ADDISON'S DISEASE FOLLOWING ENTERIC FEVER.

BY HAROLD W. EVANS, M.R.C.S. ENG., L.R.C.P. LOND.

ON Feb. 26th of this year I was called in to see a girl, 17 years of age, who said she had felt unwell for 10 days. Her temperature was 103° F. and she complained of a fulness at the lower part of her abdomen. I ordered her to bed on milk diet and found in a day or two that the case was one of enteric fever in the second week, and of moderate severity—i.e., she had from three to four loose stools a day which had the colour of yellow ochre and were occasionally streaked with blood. Typical rose spots appeared in crops. The temperature remained between 101° and 103° till March 10th when it dropped to normal, corresponding to the end of the third week from the time the patient first dated her illness. For the next week all seemed to be going well, the temperature keeping down, the tongue cleaning and becoming moist, and the motions lessening in number and improving both in colour and consistency. The following week, however—i.e., the fourth in which I had attended her and the fifth of the disease—vomiting commenced and occurred two or three times a day and once or twice a night. The vomit was of a greenish colour and of watery consistency, and did not seem to have any connexion with the diet which at that time still consisted of milk, the most marked feature being its persistency and the great difficulty I had to control it. At the time I was greatly puzzled by this symptom and thought it must be due either to irritability of the stomach as a result of the general debility caused by the enteric fever or to a gastric ulcer, though there were no symptoms of the latter, such as pain after food or blood in the vomit. About this time I noticed a marked increase in the pulse rate which made me think that the patient was going to have a relapse, but though I repeatedly took her temperature I never found any rise, nor was there any return of the other symptoms—viz., rose spots or diarrhœa.

One day in the sixth or seventh week when examining the girl's abdomen I noticed a brown discolouration of the skin immediately above the pubes. At the time I did not pay much attention to this point, thinking that as the patient and her surroundings were none of the cleanest it was probably due to the want of soap and water. The following week, however, I noticed this discolouration had increased considerably in extent and tone, and the patient remarked to me what a funny colour she was turning. On closer examination I found this staining to be made up of a number of small brown spots somewhat resembling sun-freckles. The deepest colour was immediately above the pubes, from which it extended nearly up to the umbilicus, gradually fading into the adjacent skin. I found a similar condition around the nipples and in the axillæ. Though I repeatedly examined the mucous membrane of her lips and mouth there was never any staining to be noted.

The further course of the case was one of steady decline. The pulse became weaker and weaker—in fact, for many days it was quite imperceptible at the wrist. The vomiting continued, being some days better, other days worse. There was great emaciation, though this may have been due partly to the enteric fever and partly to the patient's great disinclination to take food. Towards the end very troublesome constipation occurred and in the last week a number of purpuric spots appeared upon the chest and abdomen which showed up in marked contrast to the brown discolouration. The patient gradually sank and died from asthenia on May 19th—i.e., 11 weeks and five days from the time of my first seeing her.

As the patient lived at a distance of seven and a half miles from my house I was unable to visit and observe her as closely as I should have liked. I was not able to obtain a

necropsy to verify my diagnosis, though with the three cardinal symptoms so well marked I have little doubt in my mind that it was a true case of Addison's disease.

I should like to have the opinion of my professional brethren on the questions: Was there any direct connexion between the last and first diseases, or was it simply the case of a body debilitated by a wasting disease becoming a suitable nidus for the invasion of the bacillus tuberculosis, if, as seems generally to be acknowledged, that be the cause of Addison's disease? I examined the patient thoroughly on more than one occasion but was never able to find any tuberculous mischief elsewhere.

Littleport.

NOTE ON A CASE OF FAILURE OF RESPIRATION UNDER ANÆSTHESIA.

BY FRANK E. MARSHALL, M.B., CH.B. VICT., L.S.A.,
ANÆSTHETIST (PRO TEM.) TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

IN a recent issue of THE LANCET[1] there was a report of a meeting of the Society of Anæsthetists at which three cases of Failure of Respiration under Anæsthesia were reported by Mr. Carter Braine. As I have recently had a case somewhat on the same lines I think an account of it may be of interest to anæsthetists generally.

The patient was a well-built lad, aged 18 years, upon whom osteotomy of the neck of the femur for old fracture and subsequent ankylosed hip was being performed. The first stage and second stage passed off normally, except that perhaps the second stage was rather more prolonged and more violent than is usually seen in patients of this class. The operation had been in progress about 10 minutes, nearly an ounce of chloroform having been used in an ordinary open inhaler, when the patient suddenly stopped breathing with his pupils widely dilated and not reacting to light. The heart continued beating, as far as one could judge, quite normally. The tongue was pulled out and the jaw was jerked forwards and upwards several times with no result. The patient's head and the upper part of the trunk were hung over the edge of the operating-couch and artificial respiration was commenced, air entering and leaving the chest quite naturally. No attempt, however, was made by the patient to continue breathing. His colour remained good, though slightly pale. The pulse was very fair, but the pupils still kept widely dilated. Owing to the apparently good condition of the circulatory functions the operation was continued and completed, 10 minutes being thus occupied, during which time the above-mentioned position was maintained and artificial respiration was persisted in. After about 10 minutes the patient's breathing recommenced just as suddenly as it had stopped, the pupils returned to their normal condition, and after another two minutes he began to regain consciousness. The after events were quite normal. At no time was there any sign of approaching vomiting—the patient, indeed, did not vomit at any time after the anæsthesia. The lower jaw, I may mention, was quite flaccid; in fact, it had dropped. The heart sounds were quite normal and there was no albuminuria. Curiously enough, a week later the same patient was again operated upon, and this time a wedge-shaped piece of bone was removed from the neck and great trochanter of the femur. The operation on this last occasion occupied three-quarters of an hour, chloroform being again administered, and at no time did anything unusual occur.

To me this case appears as a true paralysis of the respiratory centre, the circulatory centre being uninterfered with; the chloroform which was used (Duncan and Flockhart's) being above suspicion.

Liverpool.

NEW MEDICAL FACULTY IN RUSSIA.—The University of Odessa has hitherto lacked a medical faculty. The necessary buildings have been already partly erected and a commencement will be made next session. There will be at first seven clinics with 195 beds, 14 ordinary and nine extraordinary professors, and nine prosectors and six assistant prosectors. The first dean of the medical faculty will be Professor Podvysotski.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

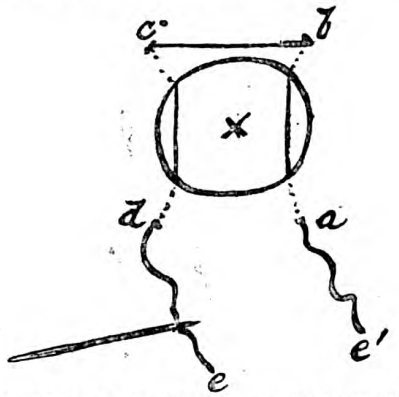
BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL.

A CASE OF OMPHALITIS RESULTING IN ULCERATION AT THE UMBILICUS; CLOSURE OF ULCER BY A PLASTIC OPERATION; RECOVERY, WITH A FIRM CICATRIX.



(Under the care of Dr. J. PINKERTON.)

FOR the notes of the case we are indebted to Mr. William Herbert, late house surgeon.

A female infant, aged one month, was on April 15th, 1898, taken by the mother to the Birkenhead and Wirral Children's Hospital for treatment on account of an inflammation of the umbilicus. The mother stated that the inflammation had been present for about a fortnight. The infant, who was born at the eighth month, was small and ill-nourished. On examination there was found to be an extensive inflammation around the umbilicus, the margin of the inflammatory zone being about two inches from the centre. The skin over this area was very red but not boggy. There was no discharge from the umbilicus, nor could a sinus be detected. A dressing of equal parts of saturated boric acid lotion and carbolic lotion (1 in 40) was prescribed, to be applied four times a day. A quarter of a grain of hydrargyrum cum creta was prescribed for internal administration every night. The child was being hand-fed and an ounce of lime water was added to each bottle of diluted milk. When seen a week after this the redness had somewhat subsided. A purulent discharge, however, had made its appearance at the umbilicus; the treatment was continued. On the 30th the discharge of pus continued, but the zone of redness had disappeared and the general health of the infant had improved. Boric acid lotion was prescribed and the grey powder was ordered to be taken every other night. The patient was not again seen till May 17th. The mother then said that on the 15th a "core" had come away from the umbilicus. On inspection a circular ulcer with roughened edges occupied the site of the umbilicus. It was about one-third of an inch in diameter and involved all the soft structures of the abdominal wall. Forming, as it were, the floor to this resulting cavity was a glistening structure which was found to be the peritoneum; but it had escaped, as it showed no inflammatory change. There was no bulging at the opening. The infant looked better. The powders were stopped.

On May 25th (with the consent of Dr. Pinkerton, the honorary medical officer) Mr. William Herbert performed a plastic operation with a view to close the ulcer as the general health of the infant seemed to permit this. No anæsthetic was given. First the edge of the ulcer was pared all round with a hernia bistoury. This instrument was chosen on account of its blunt end which could not injure the peritoneum. A clean, raw margin was obtained, as little healthy tissue as possible being removed. A curved needle, threaded with medium-sized catgut, was pushed through the abdominal wall (inferior right hand corner) about an eighth of an inch from the freshened edge (see figure, *a*). It passed through the whole thickness of the parietes, carrying the suture across the floor of the ulcer, again through the parietes, to emerge at the superior right hand corner (*b*). The suture then curved to the corresponding left upper corner and was inserted there; again carried across the floor it emerged at the left lower angle. The two ends (*e*, *é*) were then tied; good apposition was thus obtained with a certain amount of puckering. A dry dressing (double cyanide gauze) was applied and a flannelette bandage was firmly bound over this. On May 31st the suture was removed and except for a slight superficial portion union was complete. Boric acid in powder was dusted on the wound,

covered with dry lint, and the bandage was re-applied. On June 2nd union by first intention was complete. The child was last seen at the beginning of July. The cicatrix then appeared to be very firm and the flannelette binder was

The freshened edge of the ulcer is represented by the circle. *x*, Floor of the ulcer lined by peritoneum. *a*, *b*, *c* *d* indicate the course of the needle carrying the suture. *e*, *e'*, Free ends of suture ready for tying.

discontinued. The infant's general condition was good and there was no trace of any bulging at the cicatrix.

Remarks by Mr. HERBERT.—Little is said in the text-books both on surgery and on children's diseases about inflammation at the umbilicus and an unfavourable prognosis is given. The inflammation runs much the same course as elsewhere and is doubtless caused by septic organisms. In the above case the condition was no doubt a septic one, the resulting ulceration being dependent upon its severity. It would be interesting to have had more particulars about the "core" which the mother said had come away previously to the ulceration manifesting itself. Three features in the case, however, seem to be noteworthy. 1. The absence of any bulging at the site of the ulcer. This was doubtless due to the fibrous ring of the umbilicus being left more or less intact and capable of offering sufficient resistance to internal pressure. 2. The complete peeling off of the structures superficial to the peritoneum, leaving this membrane to form the floor of the resulting cavity. 3. The absence of toxic symptoms during the free employment of both carbolic and boric solutions, both of which have given rise to unpleasant symptoms in their use in infants and young children. I am indebted to Dr. Pinkerton for permission to publish this case.

LUCEA HOSPITAL, JAMAICA.

A CASE OF PROLAPSE OF THE RECTUM AND A CASE OF FIBROIDS OF THE UTERUS.

(Under the care of Dr. E. R. C. EARLE.)

THE case of prolapse of the rectum and sigmoid flexure described below may be looked upon as really an example of intussusception, for the upper part of the rectum had become invaginated into the lower. Many cases of prolapse commence in this manner, but so long as there is a sulcus between the protruding mass and the anus the case is one of intussusception. A case in many respects resembling the one appearing below was recorded by Dr. C. B. Kelsey,[1] though the intussusception had existed for a longer time. The second of Dr. Earle's cases illustrates well the fact that of all forms of uterine fibroid the most easily removed is the pedunculated subperitoneal variety, and with modern asepsis the risk to life is but slight. In this case the size of the tumours was very great and would have justified even more severe measures.

CASE 1. *Prolapse of the rectum with invagination of the sigmoid flexure; recovery.*—A feeble old coloured man, 89 years of age, was admitted into Lucea Hospital at 11.30 A.M. on Oct. 22nd, 1899, with a large tumour protruding from the anus. He stated that at 2 P.M. on the previous day, whilst straining at stool, he felt the bowel come down and that it had remained in that condition ever since. On examination it was seen that a large tumour, eight inches in length and between two and a half and three inches in diameter, protruded from the anus. The tumour consisted of prolapsed rectum and sigmoid flexure. It was conical in shape and slightly smaller at the lower end than at the middle; at the lower end there was an opening similar to a large os uteri, up which the finger could be passed. The surface of the tumour consisted of mucous membrane with concentric sulci; it was dark red in colour and much congested and swollen, with small, dark, submucous hæmorrhages. It was not strangulated at the anus and there was no odour of gangrene. The anus was lax and the finger could with ease be passed up for two or three inches between the sphincter and prolapsed bowel all round the tumour. The patient complained of severe pain in the back but not in the tumour; he was very old, poorly nourished, and very weak.

At 12 noon he was put under chloroform and the tumour, which was thoroughly cleaned and warmed, was replaced gradually and slowly without any great difficulty, owing to the lax condition of the anus. There was a slight laceration in the posterior wall of the anus. Powdered tannic acid and a morphia suppository were put in the rectum and a perineal pad and band were applied. Hot-water bottles were placed at either side and the hips were raised on a pillow.

At 6 P.M. his condition was fairly good. He had slept a little and was in no great pain. Five minims of liquor opii sedativus were given after the operation and one and a half ounces of whisky in water. He passed a good night. On Oct. 23rd, early in the morning, a stool was passed containing serous bloody fluid and small blood-clots. The bowel was washed out with boric acid lotion and a five-grain suppository of tannic acid was inserted. The patient was comfortable and was stronger. At 5 P.M., after an enema of boric acid lotion, no fæcal matter came away; the fluid was dark-coloured and was mixed with shreds of mucous membrane. The tannic acid suppository was repeated. The patient rested well during the night. There was no action of the bowels; the pain in the back was relieved, but he had pain in the left shoulder and front of the chest. At 5 P.M. an enema was administered; the stool was very offensive. The suppository was given as before. On the 25th he had slept well; the former pain was relieved, but he now had pain in the left hip. No stool had been passed during the night. The enema and suppository were administered morning and evening as before. On the 26th he had slept well. The bowels had acted once during the night; the stool was offensive. The treatment was continued. On the 27th the patient passed three liquid stools, on the 28th and 29th two, and on the 30th and 31st one each day. There were no signs of prolapse and there was no pain. On the 31st he became very weak and low and had much difficulty in speaking, but he became stronger on Nov. 1st. He was discharged from the hospital on the 5th.

CASE 2. *Large fibroids of the uterus; removal; recovery.*—A coloured woman, aged 40 years, was admitted into Lucea Hospital on June 1st, 1899, complaining of great distension of the abdomen which had gradually increased during the previous three years. On examination the abdomen was found to be much distended. There was a large moveable tumour felt in the front and right side of the abdomen, passing into the right lumbar region and upwards under the liver, filling the right half of the abdomen; the tumour was firm, elastic, and freely moveable. A second tumour similar in character, freely moveable, but of smaller size, was felt in the left lumbar region. By vaginal examination a large firm elastic tumour was felt, filling the right lateral fornix of the vagina, the cervix being small and displaced towards the left side. The tumour appeared to be situated in the right lateral wall of the uterus. As the patient was in poor health she was kept in the hospital for three weeks prior to operation in order that her physical condition might be improved.

On June 21st, at 8 A.M., chloroform was administered. A dose of castor-oil had been given the night before and a rectal enema and vaginal douche had been administered early in the morning. The abdomen had been thoroughly cleaned and asepticised and the pubes shaved on the previous day and the urine had been drawn off just before the operation. An incision was made in the mid-line from a point two inches below the umbilicus to about one inch above the symphysis and the abdominal cavity was opened; some ascitic fluid escaped. The tumours were seen to be dense, solid fibroids attached to the uterine wall by

[1] The Post-Graduate, New York, August, 1895.

short pedicles. The incision had to be enlarged in an upward direction to a point two inches above the umbilicus before the large tumour could be got out of the abdominal cavity. Its surface was covered with apron-like folds of peritoneal membrane through which coursed tortuous vessels of large size, and the omentum was adherent to it in several places. The large vessels were ligatured and cut, the adhesion bands were torn through, and the pedicle, which was about one inch long and as thick as a finger, was ligatured close to the uterus and cut and the tumour was removed. The smaller tumour on the left side was removed in a similar manner. A third tumour, of about the size of a fowl's egg, was found attached by a short pedicle to the posterior wall of the uterus under and behind the large tumour, and this was also ligatured and removed. A fourth large fibroid tumour was now clearly defined, of about the size of a man's fist, in the right half of the pelvis, apparently arising from and in the right lateral wall of the uterus, and situated between the folds of the broad ligament. It was found to be impossible to remove this large sessile tumour without also removing the uterus, and as it was not deemed to be justifiable to increase the patient's risk it was left *in situ*. Bleeding from the stump of the pedicle of the large tumour gave trouble owing to the ligature having slipped from retraction, but it was eventually controlled by stout silk ligatures. The abdominal cavity was wiped out with sponges but very little blood had escaped into it. The wound was then closed by approximating the edges of the peritoneum with a continuous fine silk suture and the abdominal wall by deep and superficial silk sutures. No drainage-tube was inserted. Tension was avoided by long strips of plaster from loin to loin. A morphia suppository was administered and she was put into bed between blankets with hot-water bottles on each side. The operation was completed and the patient put into bed at 10 A.M.

The patient was only allowed to have small quantities of warm water at intervals until 10 P.M., when milk and barley-water were given every two hours. The urine was drawn off by catheter every four hours. On the 22nd, 23rd, and 24th a vaginal douche was given each evening. Before noon each day the temperature remained normal but each afternoon and evening it rose to between 100·4° and 100 8°F., the pulse remaining at 74. The patient remained comfortable and cheerful. On the evening of the 24th small repeated doses of sulphate of magnesia were given and the diet was more generous. On the 25th the morning temperature was 101·2° and the pulse was 76. The bowels acted, a copious loose stool with much flatus being passed, the patient sleeping well afterwards. The urine was clear. The wound was dressed and was healing well. At 4 P.M. a slight, bloody, offensive discharge came from the vagina; there was no pain. The temperature was still above 101°. On the 26th the morning temperature was 99·6° and the pulse was 72. The patient passed a good stool without pain. There was a bloody vaginal discharge. The evening temperature was 101·4° and the pulse was 74. On the 27th the morning temperature was 100·4° and the pulse was 72. A copious bloody discharge was still present—bright arterial blood; there was no pain. The patient felt well. The evening temperature was 101·6° and the pulse was 74. On the 28th the morning temperature was 100·8° and the pulse was 74. The hæmorrhage from the vagina was less in quantity. An enema was given and a slight amount of flatus was passed. The evening temperature was 101·2° and the pulse was 70. Ice was applied locally in the vagina. On the 29th the morning temperature was 99° and the pulse was 70. At 4 A.M. a sero-purulent discharge came from the lower end of the wound and soaked the dressings. There was a firm lump felt in the uterine region. The lower stitches were removed to allow free exit for discharge. A probe inserted in the sinus passed upwards and backwards in the mid-line. The hæmorrhage from the vagina was much less. The evening temperature was 99·2° and the pulse was 70. On the 30th the morning temperature was 98·2° and the pulse was 70. Sweet pus was still discharging from the sinus. The lump in the uterine region was smaller. The temperature was normal all day. The vaginal discharge had almost ceased. On July 1st all the sutures were taken from the wound except three deep middle ones. After this the discharge gradually ceased and the temperature and the pulse remained normal. The patient convalesced rapidly, made an uninterrupted recovery, and was discharged from the hospital on August 13th.

Remarks by Dr. EARLE.—Case 1 was undoubtedly one of invagination of the sigmoid portion of the colon into the rectum, with prolapse of the invaginated bowel through the anus. The lower two or three inches of the rectum were not prolapsed, as was proved by the insertion of the finger through the anus between the sphincter and the tumour, when the fold between the two layers of rectal mucous membrane could be easily felt round the whole circumference of the tumour. The extreme age (89 years) and the weak condition of the patient, the large amount of prolapsed bowel, and the interval that elapsed before the prolapsed bowel was replaced, namely, 22 hours, all tended to increase the gravity of the patient's condition, and the favourable result must be considered noteworthy, as the mortality rate in these cases amongst the aged and infirm is as a rule very high.

In Case 2 the three tumours weighed respectively 6 lb. 6 oz., 2 lb. 2 oz., and 2 oz., and were composed of dense fibrous tissue. The tumour in the right lateral wall of the uterus became much smaller in size before the patient left the hospital. The continued rise in the temperature was, I think, due to the suppuration which occurred in the locality of the large silk ligature, for the temperature became normal as soon as efficient drainage of pus occurred. The temperature rose only once above 101° and the pulse never went beyond 80. I was ably assisted during the operation by Dr. C. M. Phillips of Philadelphia and Sister Annie Douglass of St. Bartholomew's Hospital, to whom I desire to convey my thanks for their valuable aid.

Medical Societies.

HUNTERIAN SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held on April 11th at the London Institution, the President, Dr. DUNDAS GRANT, being in the chair.

Dr. BUTLER HARRIS showed a case for Diagnosis—an infant with a Sublingual Swelling.—Dr. F. J. SMITH said that he had no doubt that the lump was some form of developmental error, most probably a persistent thyroglossal duct. He thought that this was so because of its position in the middle line of the body and from the softish, cystic feeling of the lump. For treatment he advised waiting till the child was a little (a year or more) older and then radical excision.—Dr. RAWES considered it to be a case of venous nævus and he based his diagnosis upon the presence of distended veins in the neighbourhood and upon the fact that the tumour could be so easily compressed between the forefingers.—Mr. J. H. TARGETT suggested that it was a nævoid growth.

Sir HUGH BEEVOR showed a case of Hemianopsia occurring in a man 49 years of age. In September, 1897, he had a sudden attack which left him with much loss of sensation on the left side, slight left paralysis, and impaired intelligence. In November, 1897, he was under Dr. Ferrier's care and the record then made was to the effect that his family history had been good and that he had had no ailment but syphilis 17 years before. A few months previously he had noticed a sudden loss of sensation on the left side and his eyes were so affected that in his work he used to spoil material by not cutting it properly; he had noticed little alteration since the attack commenced; the loss of power in his arm and leg had been increasing; he had no loss of consciousness at the time of the attack and had no headache or vomiting. He was a well-built man, looking stupid and listless. Tests of sensation gave the following results: the taste and smell were normal; the hearing was less acute on the left side after removing the cerumen; vision—hemianopsia, left, complete to middle line; analgesia of the left arm and leg; anæsthesia of the face, arm, and leg; and loss of muscular sense in the arm and leg. He walked with a slight stagger and a tendency to fall backwards and to the right. The grasp of his left hand showed loss of power. Ankle-clonus and exaggerated knee-jerk were present. Ophthalmoscopic examination was normal. Cranial tenderness on deep pressure was elicited over the right parietal eminence. In February, 1900, he was attacked

with vomiting and left-sided convulsions and with conjugate deviation of the eyes to the left, followed by paralysis of the left side and of the right external rectus oculi; for a few days he was semi-conscious. In a few weeks the ocular movements became normal and the patient's condition seemed little altered by his recent attack.—Dr. F. J. SMITH said that from the absence of neuritis and from the stationary nature of the symptoms for over two years the lesion was probably a softening, either thrombic or embolic. He thought a tumour was ruled out by these facts. He thought that the lesion must be more central than in the optic tract. The staggering in the gait might possibly be due to hemi-paresis of sensation leading to incoördination, and not necessarily to subjective unsteadiness. He was inclined to place the lesion at the hinder part of the posterior limb of the capsule (the sensory crossway), believing that a single lesion here might cause all the symptoms, and if possible he would prefer to ascribe the symptoms to one lesion rather than to multiple lesions. If the gait were ascribed to cerebellar influence he thought that the hemianopsia would require a second focus of destruction to explain it, as it was so very complete.—Sir HUGH BEEVOR said that from the recent attack it seemed evident that a tumour was present.

Dr. F. J. SMITH showed, by permission of Dr. F. WARNER, a case for which he thought a provisional diagnosis of Friedreich's Ataxy was most likely. The patient was a girl, 14 years of age, the eldest of four children, and was quite well till she reached the age of seven years when she had measles. After the measles she was noticed to have twitching of the limbs, which was diagnosed as chorea. With this twitching there was noticed a difficulty in walking and this, it was said, had got steadily worse. In fact, at the end of 1899 she was still thought to have chorea. Coördination was markedly interfered with in all her limbs; she could not stand alone, much less walk, even with her eyes open; with the hands she could pick up small objects fairly naturally and easily so long as her eyes were open, but on closing the eyes she completely lost the power of touching her nose with the finger and could not locate her limbs at all. There were no knee-jerks and no ankle clonus; on testing the plantar reflex the big toe was first extended. The cranial nerves seemed unaffected, though her intellectual faculties were somewhat deficient.—Mr. TARGETT called attention to the marked degree of scoliosis present in this case and the resemblance which it bore to the trophic scoliosis of syringomyelia. In the latter affection scoliosis occurred in more than half the cases. Pes cavus was present in both disorders, though it was more characteristic of Friedreich's ataxy. Neuropathic arthritis, such as was well known in connexion with locomotor ataxy and syringomyelia, had not been met with in Friedreich's ataxy.

THE PRESIDENT showed a case of Syphilitic Lesion of the Facial Auditory and Spinal Accessory Nerves. The patient, a man, 41 years of age, had come under Dr. Grant's care in June, 1899, on account of extreme deafness in the left ear. The left side of the face was almost completely paralysed as was also the left half of the palate and the left vocal cord. He had, therefore, a lesion involving the facial, the auditory, and the spinal accessory nerves simultaneously. In July, 1890, he fell down on his way to his work and was unconscious for some three days, and on recovery was found to have some weakness on the right side of the body. Two years later he had a second attack which developed suddenly in the middle of the night and left him with paralysis of the left side of the face, complete deafness in the left ear, hoarseness of voice and giddiness. The history of acquired syphilis was elicited and there seemed little doubt that the combination of nervous conditions was due to a syphilitic lesion either in the medulla oblongata or external to it at the point of exit of the nerve mentioned.

THE PRESIDENT also showed a case of Rhinoscleroma, occurring in a woman, 26 years of age. A microscopic preparation of a portion of the tissue when removed was made by Mr. Wingrave, and Dr. St. George Reid made a cultivation which, he considered, answered to that typical of rhinoscleroma, as showing the capsuled bacillus.

Dr. W. H. KELSON showed a case of Lupus of the Nose, Palate, and Tongue.

Dr. J. H. SEQUEIRA showed a case of Birth Palsy occurring in a male infant, aged four months, the first child of healthy parents. There was no history of syphilis. The labour was apparently an easy one, the mother being attended by a midwife. It was stated that the child was born "head first," and so far as could be gathered no undue efforts were necessary for delivery. Immediately after birth it was noticed that the child's fingers were bent into the palm and that the left elbow could not be straightened.

Dr. J. H. SEQUEIRA also showed a case of Lupus Erythematosus occurring in a woman, aged 21 years, who had suffered from the disease for two years. The eruption began as two symmetrical patches just in front of each ear and gradually spread on to the cheeks.

Facilities have been provided for Fellows to dine together before the meetings at an hotel near the London Institution. This is found to be a great convenience to Fellows living at a distance and is quite in accordance with the social traditions of the "Old Hunterians."

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

The Hill Stations of India as Health Resorts.

THE annual meeting of this society was held on May 30th, when the members dined together. A conversazione was subsequently held at 20, Hanover-square with a reception by the President, Dr. J. IVOR MURRAY.

Sir JOSEPH FAYRER, Bart., F.R.S., K.C.S.I., gave an address on the Hill Stations of India as Health Resorts. He wished, he said, to consider these stations not merely in reference to the treatment of disease and convalescence but also as resorts in which the European might preserve his health and avoid the physical deterioration which inevitably resulted from protracted residence in the plains; places indeed, where it seemed even possible that he might take root, thrive, and propagate his race—a subject of ever-widening interest to our rapidly increasing population. For this there were grounds of belief that the prospects of success were not altogether unfavourable, though so far no conclusive proof of it was forthcoming. Past history, however, showed that colonisation by the unmixed European races in the plains of India was impracticable. In the very rare instances in which the third generation had been reached it had evidently attained its utmost desirable limits, whilst of the Portuguese who preceded us no descendant unalloyed by native blood could be said to exist. The physiographic characters of British India were next described, there being three natural divisions: (1) the Himalayan and sub-Himalayan region; (2) the Indo-Gangetic basin and deltas; and (3) the Peninsula proper formed by the elevated plateau of the Deccan bounded on each side by the Ghauts and the littorals between them and the ocean. In these areas there were very many varieties of climate which depended upon the latitude, elevation, and soil. There were three seasons in the year—the hot season, which extended from March to June; the rainy season, which extended from July to October; and the cold season, which extended from November to March. These seasons varied considerably according to the latitude and elevation. They were also greatly influenced by the monsoons or rain-bearing winds. The monsoons did a great deal to determine the conditions of climate and health as well as the production of food. They resulted from the northern flow of air bearing moisture from the ocean and they were more or less deflected or modified by the physical conditions of the country over which they passed. The south-west monsoon was the great carrier of rain in India, which it deposited upon the Western Ghauts, where it first impinged, and where the greatest amount fell. Then passing over extensive tracts of desert land it came in contact with the Himalayas where a large fall took place. Every variety of climate, Sir James Fayrer said, could be met with in India. Malaria was widespread in the plains and here no Europeans could exist for any continuous length of time, but there were many hill stations where they could live, and many others which had never been fully explored or taken advantage of, and he believed that such an investigation as this would form a worthy object for this society, the opinion of which would carry much weight. There were, for instance, the elevated plateaux of the Khasia, and the Syntea Hills between Bengal and Assam, which were at a height favourable to the European constitution, and the range of high country parallel to the Ganges presented fine table-lands at Sohagpore, the elevation of which had been estimated at from 3000 to 5000 feet. Both of these were favourably

spoken of by the late Inspector-General MacLelland. The district of Ramghur in the Saugor and Nerbudda territories and other regions were also mentioned as being only imfectly explored. Although much had been done since Dr. MacLelland wrote there was good reason to believe that in the vast mountain ranges and table-lands of India the physical and climatic conditions necessary for the preservation of health, and perhaps even for the permanent colonisation of the European, would be found to exist to a much greater extent than had hitherto been supposed. As illustrative of the extra-tropical (i.e., the Himalayan) districts Darjeeling, Naini Tal, Simla, and Mount Abu were described, and as examples of the tropical districts Mahableshwar, Matheran, and the Nilgiris. Only a brief account of these could be given, but it touched the fringe of a large subject, one which might with advantage be investigated by the British Balneological and Climatological Society.—The PRESIDENT, who spoke in very high terms of the address (to which, he said, those present had listened with much pleasure) proposed a vote of thanks to Sir Joseph Fayrer.—This was seconded by Dr. ROBERT BARNES and carried by acclamation.

A collection of meteorological instruments was shown by Messrs. Negretti and Zambra, surgical instruments were exhibited by Messrs. Allen and Hanburys, drugs by Messrs. Oppenheimer, books by Mr. H. K Lewis, Mr. H. Kimpton, and Mr. Bale, and dietetic preparations by Messrs. Van Abbott and Sons. Excellent music was provided by the Leoni Ladies' Quintette.

ISLINGTON MEDICAL SOCIETY.—A meeting of this society was held on May 15th, at 25, Highbury-place.—Dr. Ford Anderson opened a discussion on the subject of Placenta Prævia, pointing out how dangerous this variety of complex labour was to the mother and especially to the child, the maternal mortality being 5 per cent. and the infantile mortality 90 per cent.; the maternal mortality, however, was one-third less in cases of partial placenta prævia than in cases of central placenta prævia (Glasgow Maternity Hospital). The appalling infantile mortality was largely due to prematurity, but where it was not so there was hope that it might be reduced by better treatment. The pathology of placenta prævia was described as were the peculiarities of the lower uterine segment which indicated that it was useful as a passage only, not possessing contractile power and therefore fitly called the "dangerous placental seat." The diagnostic signs of placenta prævia were then described and their importance as a prelude to treatment was pointed out. Hæmorrhage was generally the first sign and suspicion was aroused by its apparently causeless occurrence, often when the patient was lying down and sometimes when she was asleep. The history of a case of placenta prævia might differ in no respect from any other case till the middle of the ninth month of pregnancy, when a hæmorrhage occurred which was really unavoidable and was generally large and sometimes fatal. If this late appearance of hæmorrhage were the invariable rule there would not be so much divergence with regard to treatment. More frequently there were warning hæmorrhages in the course of pregnancy from accidental separation of the placenta and many miscarriages were probably due to this cause. Vaginal examination showed bogginess of the lower uterine segment and absence of ballottement; if the placenta were felt that was pathognomonic. Abdominal palpation was most useful to those who practised palpation in all cases. The method as described by Pinard and others was best and with practice there was no difficulty in diagnosing the presence of the soft placenta below the head in the pelvic excavation. In the treatment it had been the practice to temporise till the child was viable, that is, till the seventh month; and perhaps where the patient could be kept under constant skilled supervision in a hospital this was permissible if the hæmorrhages were neither too frequent nor too great, but, considering the small chance to the child and the great risk to the mother from waiting, it was better in a case of early pregnancy with diagnostic signs of placenta prævia to empty the uterus as quickly as possible compatible with safety. This was certainly the best course for the patient as well as the practitioner. In general practice the ordeal of waiting was very trying, and no one who had gone through it once would care to do so again. The details of treatment as generally applied were next described—that is to say, bi-polar version preceded in cases of contracted cervix by puncture of the membranes and the use of the cervical plug; but, contrasted with the traditional methods, the Champetier de Ribes bag was eulogised as an invention which could be used at almost any stage of delivery in placenta prævia. It was an inverted cone when introduced, the apex being at the os internum and it formed a gentle and uniform dilator of the os uteri; it imitated the bag of the membranes, and the base of the larger Champetier de Ribes bag was of such a size that when it had passed through the os delivery could be completed. By traction on the pipe the uterine sinuses could be compressed and, if necessary, the traction could be maintained for many hours by a light weight. The introduction into the amniotic sac, after puncturing the membranes, by the special forceps, was always easy, even when the os was dilated only to the size of little more than one finger, and the bag should be previously scrubbed with soap-and-water and a nailbrush and should be dipped in carbolic solution (1 in 20). This was the rival treatment to sponge tents and even to turning. Dr. Anderson referred to two cases in which he had used the bag. In one the placenta was marginal and when he was called in the night he found the patient flooding freely and the os uteri admitting little more than one finger. He introduced the bag immediately after rupturing the membranes, distending it with water by means of a syringe, and by using ergot and a bandage and by traction on the pipe he controlled the hæmorrhage for several hours when the bag was expelled, and as the child lay transversely he turned and delivered. It seemed all so simple compared to the old treatment. Referring to the objections raised to the use of the bag he remarked that in order to avoid sepsis it was well to begin by removing clots at the cervix by a douche. As the bag was introduced into the amniotic sac it took the place of water which escaped and there was no recorded case of rupture of the uterus. It was well, however, to ascertain previously the capacity of the bag and to fill the bag slowly, stopping during uterine contractions. There might be some risk of rupture in induction of premature labour, as the membranes were not previously ruptured, but here a small-sized bag might be used in the first instance. There was no doubt that displacement of the presenting head might be caused by the bag, but this could be rectified on withdrawal, if not before. Already statistics showed an improvement as regards infantile mortality—which in Dr. G. F. Blacker's collected cases was 54 per cent.—with no increased risk to the mother, and Dr. Anderson concluded by expressing his belief that this encouraging result would be maintained and improved as the value of the Champetier de Ribes bag became more widely recognised.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—The annual meeting of this society was held on May 24th when the following officers were elected for the ensuing year:—President: Dr. A. J. Harrison. Vice-Presidents: Dr. H. A. G. Brooke, Mr. Alfred Cooper, Dr. H. Radcliffe-Crocker, Sir George Duffey, Dr. Robert Liveing, Dr. J. F. Payne, and Dr. J. H. Stowers. Council: Dr. P. S. Abraham, Dr. Alfred Eddowes, Dr. W. T. Freeman, Mr. Hope Grant, Dr. A. J. Hall, Mr. T. J. Hitchins, Dr. H. H. Phillips-Conn, Dr. Leslie Roberts, Dr. Arthur Shillitoe, Dr. R. Travers Smith, Dr. F. Rufenacht Walters, and Mr. Campbell Williams. Treasurer: Mr. George Pernet. Honorary secretaries: Dr. C. Herbert Thompson and Dr. E. Graham Little.—Clinical cases were shown by Dr. Stowers, Dr. Abraham, Dr. Eddowes, and Dr. Freeman.—The President read an inaugural address on the subject of Erythema Nodosum. His experience had caused him to question its supposed causal connexion with acute rheumatism.—Mr. W. Anderson read a paper on the Chief Constitutional and Local Conditions Associated with Seborrhœa. Seborrhœa oleosa was a physiological condition giving rise to disease only in so far as the increased secretion offered a nidus for bacteria. Coronal baldness was usually due not to seborrhœa or parasitic invasion but to senile change. Alopecia areata was not in his experience associated with seborrhœa. Seborrhœa sicca was an inflammatory disease due to parasitic invasion; the baldness in such cases was usually in the first instance temporal. Seborrhea sicca favoured the development of other diseases, such as acne vulgaris and rosacea, seborrhœic dermatitis, lupus erythematosus, pityriasis rubra; and influenced the distribution of other affections, such as lichen circinatus.—The President, Dr. Abraham, Dr. Eddowes, Dr. Stephen Mackenzie, Dr. Radcliffe-Crocker, Mr. Pernet, and Dr. W. B. Warde

joined in the discussion.—Numerous drawings and photographs were exhibited, notably a collection of drawings shown by Dr. Radcliffe-Crocker and a series of photographs by Dr. Arthur Hall.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held on June 1st, Dr. J. B. Ball, President, being in the chair.—A case of Retro-peritoneal Abscess was shown by Mr. Stephen Paget.—A case of Myxœdema in a Child, aged five and a half years, illustrated by three photographs, was shown by Dr. Leonard Guthrie. (The case was discussed by the President, Mr. McAdam Eccles, Mr. George Pernet, Mr. Rickard Lloyd, and Dr. P. S. Abraham, and Dr. Guthrie replied.)—Mr. L. A. Bidwell showed a case of Arthrectomy of the Elbow, and remarks were made upon it by Mr. McAdam Eccles.—Mr. McAdam Eccles showed: (1) Cases illustrating Swellings in the Digits—(*a*) Tuberculous Enlargement of the First Phalanx of the Thumb and (*b*) a Cystic Tumour of the Middle Finger; and (2) cases of Injuries about the Elbow-joint—(*a*) a case of Separation of the Lower Epiphysis of the Humerus and (*b*) a case of Fracture of the Olecranon. Skiagrams of all these cases were shown by Dr. F. H. Low and remarks were made upon them by Mr. Bidwell and Dr. A. H. W. Clemow. Mr. Eccles replied.—Dr. Abraham and the President showed a case of Tuberculous Disease of the Skin and Mucous Membranes.—Dr. Abraham also showed a case of Acute Erythematous Lupus.—The cases were discussed by Mr. Pernet, Mr. Bidwell, and Mr. Rickard Lloyd. Dr. Abraham replied.—Mr. Pernet showed Sections of Leprous Nodules containing Bacilli.

Reviews and Notices of Books.

Archives of Neurology and Psycho-pathology. Volume II. Nos. 3 and 4. 1899. Issued from the New York State Hospitals Press at Utica, New York, March, 1900. Royal 8vo, pp. 265 with 16 Plates and several Illustrations in the text. Price $3.00.

THE present volume contains a number of papers dealing with various subjects of interest to the alienist and neurologist. The scope of the general ground covered is wide, extending from such matters as embryo-chemical studies on the developing egg to clinical studies in epilepsy and cerebral palsies. Dr. L. Pierce Clark, Assistant Physician to the Craig Colony for Epileptics, New York, contributes three papers comprising a series of Clinical and Pathological Studies in Epilepsy. The first in the series deals with the subject of Exhaustion-Paralysis in Epilepsy, and after a brief historical sketch there follows a discussion of the various hypotheses and theories of exhaustion-paralysis together with illustrative cases from personal study and from medical literature. The second and third papers deal respectively with the comparatively rare association of Paramyoclonus Multiplex and Epilepsy and the still rarer clinical phenomenon the Hypertrophic Form of Infantile Cerebral Palsy. Several of the cases of exhaustion-paralysis have yielded opportunity for study after death by anatomico-pathological methods. Dr. Clark's papers are a valuable contribution to the study of the causation and sequelæ of epilepsy and much interesting information is brought together in his three articles. The critical digest of cases in the form of abstracts from the literature of the subject must have involved much labour and will be of great value for reference. 47 illustrations in the text and five photographic plates accompany the paper on exhaustion-paralysis. The next two papers on Paramyoclonus Multiplex associated with Epilepsy and on Hypertrophic Infantile Cerebral Palsy and Phocomelos associated with Epilepsy have a more limited interest, but both show the same excellent qualities of lucidity, fulness of information, and excellence of illustrations and plates characteristic of the first paper.

Dr. P. A. Levene and Dr. I. Levin supply a paper on the Absorption of Proteids based on work at the Physiological Laboratory of Columbia University, New York. As regards digested proteids it was till recently very generally believed that they were taken up from the alimentary canal by the intestinal blood-vessels into the general circulation. This view at first controverted by Leo Asher has since been confirmed by L. B. Mendel. Dr. Levene and Dr. Levin experimented with iodoproteid, a pure proteid substance obtained from the white of eggs, and their experiments tend to confirm the older view of the absorption of digested proteids by the intestinal blood-vessels as against the view of absorption by the intestinal lymphatics. The next subject—viz., Embryo-chemical Studies, by Dr. Levene—deals with the distribution of nitrogen among the various egg proteids at different stages of development of the ovum and is only a preliminary communication.

Messrs. Richard Weil and Robert Frank publish a very brief paper on the Theory of Neuron Retraction, a subject much discussed of recent years among psychologists and neurologists, and they seem to conclude that the evidence is not positive enough as yet to furnish a satisfactory basis for the explanation of facts. Dr. P. A. Levene furnishes a preliminary communication on the Chemical Relationship of Colloid, Mucoid, and Amyloid Substances, showing that the acid radicals common to these substances are very similar to each other, though the question of their identity is still unsettled. Mr. Ward A. Holden contributes a paper on the Changes in the Optic Nerve produced by Acromegaly, as exemplified in three cases. All three patients were middle-aged women, and the symptoms of compression of the optic chiasma and degeneration of the optic nerve fibres following the growth of the pituitary tumour are clearly described and illustrated by a plate. The present volume of the Archives is equal in interest to its predecessors and speaks well for the progress of neurology and psycho-pathology in the United States.

Anæsthetics: their Uses and Administration. By DUDLEY W. BUXTON, M.D., B.S. Lond. Third edition. London: H. K. Lewis. 1900. Price 6*s*.

IN the third edition of his well-known work Dr. Dudley Buxton has made many useful additions and generally brought the subject up to date. In the introduction he gives an account of Dr. G. B. Flux's open method of administering nitrous oxide, not hitherto published in any text-book, and later he describes Dr. F. W. Hewitt's gas and oxygen apparatus with the mode of its employment. Other important additions are descriptions of new methods of prolonging nitrous oxide anæsthesia, Schleich's solutions for general anæsthesia, and his infiltration method of local anæsthesia.

The physiological chapters have been revised and amplified, the most recent researches of Waller and others being mentioned. This part of the work is particularly good and the accounts of the physiological actions of the various anæsthetics are briefly but completely and clearly given. Dr. Buxton goes fully into the important question of the choice of an anæsthetic in various conditions and for different operations. We are glad to see that he advocates the use of ether preceded by nitrous oxide for ordinary surgical work unless there is good reason against it, and also that he recommends the same anæsthetics in operations for adenoids. In the account of the method of using Clover's portable regulating inhaler some authorities will not agree with Dr. Buxton when he directs that during induction the ether chamber should be rotated till the indicator points to F, and that it should afterwards be brought back to 2 and there kept till the operation is over; in many cases there is no need to go beyond 2 or 2½ during induction, and after ten minutes or so most patients can be kept

satisfactorily anæsthetised with the indicator half way between 0 and 1. In this section the possibility and the importance of avoiding cyanosis by frequently raising the face-piece are very properly insisted on. It is a pity to advise the administrator to adopt the practice of blowing out the bag himself. It can be satisfactorily distended by raising the face-piece during inspiration and firmly applying it during expiration.

A very good account is given of the various forms of ether inhalers and their uses. In the section on Chloroform we should like to see more stress laid on the importance of maintaining the pupil at its greatest possible degree of contraction with reference to the fact that a contracted pupil is one of the most valuable signs of safety, and also on the fact that the size of the pupil is a good measure of the depth of anæsthesia. We see no mention of the fact that chloroform is borne much better and that the liability to cardiac and respiratory depression is much less if the administration is begun with ether or gas and ether, so that the patient is efficiently stimulated. There can be no doubt of the advantage of this succession of anæsthetics in long abdominal operations.

The directions for the preparation of patients for anæsthesia and for the after-treatment, and the description of the measures to be adopted in alarming complications and emergencies, are exceedingly good and practical. Dr. Buxton rightly attaches great importance to the horizontal posture during and after the administration of chloroform.

A good plan is adopted in the introduction, where suggestions are given as to the order in which the different chapters are to be read. This is likely to be useful to students who are studying the subject for the first time. The illustrations are admirable.

The Nervous System of the Child: Its Growth and Health in Education. By FRANCIS WARNER, M.D., F.R.C.P. Lond. London: Macmillan and Co. 1900. Pp. 233. Price 4*s.* 6*d.*

DR. WARNER'S name is so well known in connexion with child study that whatever he writes will be read with interest by those concerned in the education and upbringing of children. In this book Dr. Warner describes the brain and body in infancy, tracing the gradual development of the mental faculty from birth onwards to school age. He very rightly insists that the training of a child must begin from birth and shows how the formation of regular habits as to sleep and bodily requirements and the cultivation of a healthy state of mind prepare the child for a methodical life later. A very clear and excellent chapter dealing with the food, clothing, and the general hygiene of childhood ought to be helpful to anyone in charge of the young. Wrapped up in not always clear language and illustration is the sound idea that children should be taught to use their senses in an orderly manner when called upon to form judgments; "the confusion arising from seeing, hearing, and feeling at the same time" must be removed by "methodical procedure in looking carefully, attending to what may be felt in handling objects, and in hearing distinctly what is said."

Amidst much that is interesting and profitable to teachers and parents, to whom the book is primarily addressed, there is not a little that suggests criticism. Many of the methods proposed for mental training seem to be more adapted for dull or feeble-minded children than for those of average capacity. We cannot imagine a normal child either submitting to, or profiting by, such instruction as is recommended on page 159: "Make him hold out his hand and move the fingers A, B, C, D, E, one at a time in succession, and again all together; then, dropping his hand, look at you while you say and he pronounces the word 'five.' Make him turn his eyes to five similar objects at equal distances apart, then look at you and say 'five'; thus in each case you make five impressions by muscle sense and teach the numeral. Put an ounce weight in his hand, add others up to five ounces, and make him say 'five'; he feels by his muscles the strain added by each weight and feels the 'five' heavier than the one." A normal child who was old enough to appreciate and carry out such directions would already know "how many beans made five."

The Norwegian North Polar Expedition, 1893–1896, Scientific Results. Edited by FRIDTJOF NANSEN. Vol. I. London: Longmans. viii.+16+26+53+137 pp. 46 Plates. 1900. 40*s.* net.

THIS, the first instalment of the account of the results of the *Fram* expedition, forms a large and handsome quarto volume. It commences with an account of the *Fram* itself, which is illustrated by three plates portraying the structure of that vessel; this is followed by a sketch of the geology of Cape Flora, Franz Josef Land, including a description of fossil plants and animals. The purely zoological part of the work contains a report upon the birds collected and the crustacea. Dr. Nansen himself, with the collaboration of the well-known ornithologist Professor Collett of Christiania, deals with the birds, and it is almost unnecessary to state that Professor G. O. Sars is responsible for the crustacea. As might well be supposed, the ornithological section is not interesting from the point of view of new species; so much has been done in this part of the world that new forms could hardly have been expected to turn up. In the crustacean section, however, Professor Sars finds much that is new, especially among the smaller forms, and most particularly among those minute creatures belonging to this order known as copepoda. These are illustrated in 36 plates by the author himself, who is a skilled draughtsman and, we believe, always draws and lithographs his own plates.

LIBRARY TABLE.

Golden Rules of Ophthalmic Practice. By GUSTAVUS HARTRIDGE, F.R.C.S. Eng., Senior Surgeon to the Royal Westminster Ophthalmic Hospital. Bristol: John Wright and Co. London: Simpkin, Marshall, and Co. May, 1900. Pp. 69. Price 1*s.*—This little duodecimo volume is one of a series which may be very well carried in the pocket of the country practitioner's carriage to be consulted when occasion may require. The author, who has had large experience, has compressed much information into a small compass. The diseases mentioned are placed alphabetically and the diagnosis and treatment are given clearly and concisely. The treatment might in some cases be more fully given with advantage and without materially increasing the size of the book.

Manual of Chemistry, Inorganic and Organic, with an Introduction to the Study of Chemistry. By ARTHUR P. LUFF, M.D., F.R.C.P., B.Sc. Lond., F.I.C., and FREDERIC JAMES M. PAGE, B.Sc. Lond., F.I.C., A.R.S.M. London: Cassell and Co. 1900. Pp. 541. Price 7*s.* 6*d.*—Among the many text-books of chemistry written mainly for the use of the medical student perhaps few have been more favourably adapted for hospital schools than the work now before us. The first edition, however, as we pointed out in THE LANCET of July 16th, 1892 (p. 145), contained certain serious errors of omission and commission. Otherwise the plan of the book was excellent. We are glad to see that the whole work has now been thoroughly corrected and revised and brought up to date. By medical students, indeed, such a treatise will be much appreciated in that it provides them with the

work which they require for examination purposes without being essentially a cram book. It must be confessed, however, that the descriptions in many instances are very bare. Short accounts are added of some of the organic compounds of the antipyretic and analgesic series, such as antipyrine, acetanilide, and phenacetin. Another distinctly useful feature is the frequency with which equations are employed in the descriptions of the various chemical reactions. In addition to the theoretical portion of the book a series of tables is provided for the detection of simple salts containing the metals included in the syllabus of both the Preliminary Scientific and Conjoint Board examinations. Some notes are also given on the preparation of those salts that now find a place in the practical work of the latter examination. We have no doubt that in its revised form this manual will be in greater demand than it has been in the past, and it may be confidently recommended to the student now that it is sound in theory and in fact.

The Absent-minded Beggar. By RUDYARD KIPLING. London: The Printing Arts Company, Limited. 1*s.*—The Printing Arts Company, Limited, have published a "Royal Edition" of this wonderfully popular poem illustrated by Gordon Browne, Frank Dadd, and W. Hatherell. The printing, which has been done on an Orloff press, is a curiosity, as the eight different colours have been obtained in one impression. The publishers estimate that in an edition of 100,000 copies their profit would be 3*d.* per copy and they intend to give 3*d.* upon every copy sold to the "Absent-minded Beggar Relief Fund" organised by the *Daily Mail.*

Mona Maclean. By GRAHAM TRAVERS (Margaret G. Todd, M.D. Brux.). Fifteenth and cheaper edition. Edinburgh and London: William Blackwood and Sons. 1900. Pp. 474. Price 2*s.* 6*d.*—We reviewed the first edition of Miss Todd's novel in our issue of Dec. 17th, 1892. When a book has reached its fifteenth edition it is needless to say any more, but we may add that the publishers should be thanked for putting a cheap edition of a clever and wholesome story within the reach of everyone.

Paris. Guides Conty Series. English edition. Paris: 12, Rue Auber. Pp. 336, with appendices and index. Price 2*s.* 6*d.*—The Guides Conty are so well known and so trustworthy that it is hardly necessary to say anything more about them. However, as in all probability many English and Americans will flock to Paris during this year we may remark that they will find almost everything in this guide that they can require. In addition, if the traveller will read a work called "The Stones of Paris" which has been recently published he will learn a great deal about the history of the city which will add to the interest of his visit.

JOURNALS.

Annales de Gynécologie et d'Obstétrique. March and April, 1900. Paris: Steinheil.—In the March number Dr. I. Ronsse discusses the presence of acetone in the urine during pregnancy. He concludes that a minute quantity of acetone is normally present in the urine. The amount is increased in almost all cases during the last 15 days before delivery, as a result of labour, especially when this is prolonged, and during the puerperal period. The author is unable to confirm the statement that the amount of acetone in the urine increases as a result of the death of the fœtus. Dr. Gouillioud contributes a paper upon Salpingostomy and Dr. Labusquière a clinical review of a case of Accidental Hæmorrhage reported by Dr. Fieux, in which condition the latter advocates manual dilatation of the cervix as giving better results than the use of the Champetier de Ribes bag. A summary of the obstetrical and gynæcological communications made to the Anatomical Society of Paris and the usual bibliography conclude the number.

The April number contains a paper upon two cases of Spontaneous Rupture of the Uterus and their Surgical Treatment in which MM. Weiss and Schuhl recommend in the presence of symptoms pointing to a complete rupture of the uterus the termination of the labour as rapidly as possible by the natural passages and the performance of laparotomy. If possible the tear should be sutured, otherwise supra-vaginal or total hysterectomy should be carried out. Dr. A. Fraikin contributes an exhaustive paper upon Sclerocystic Changes in the Ovaries. The number also contains a paper upon Dystocia caused by Uterine Fibroids by M. G. Lepage, and an account of an interesting case of Fibromyoma of the Abdominal Portion of the Round Ligament by M. André Claisse. The proceedings of the Society of Obstetrics, of Gynæcology, and of Pædiatrics of Paris and the tri-monthly bibliographical index are also given.

ARRANGEMENTS FOR THE CELEBRATION OF THE CENTENARY OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN extraordinary meeting of the Council was held on May 31st, the President, Sir WILLIAM MACCORMAC, Bart., K.C.V.O., being in the chair.

A report from the Centenary Committee was received and adopted. The following arrangements have been made:—

On Wednesday, July 25th, there will be a conversazione at the College from 9 to 12 P.M.

On Thursday, July 26th, a centenary meeting will be held in the theatre of the University of London, Burlington-gardens, at 3 P.M. The President will give an address and the Honorary Fellowships will be conferred. On this occasion academic costumes, uniforms, and orders will be worn. At 8 P.M. on the same day a festival dinner will be given in the Hall of Lincoln's Inn by kind permission of the Benchers.

On Friday, July 27th, the Right Hon. the Lord Mayor will give a conversazione at the Mansion House.

In addition to these arrangements Professor Stewart, the conservator, with Mr. S. G. Shattock, the pathological curator, and Mr. R. H. Burne, the anatomical assistant, will be in attendance each morning between 11 A.M. and 1 P.M. to conduct visitors over the museum.

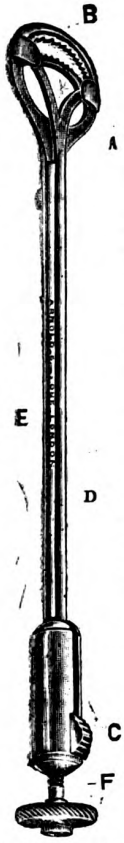
In the library a collection of objects of interest in connexion with the history of the College will be displayed, and Mr. V. G. Plarr, the librarian, will be in attendance each morning to receive visitors.

At the Examination Hall Dr. T. G. Brodie, director of the laboratories, will give lantern demonstrations of the work done in the laboratories.

Many invitations have been issued to foreign and colonial surgeons, and numerous invitations have also been sent to persons of distinction residing in Great Britain and Ireland.

A limited number of seats at the dinner will be reserved for Fellows and Members of the College and the price of the dinner ticket will be two guineas. Applications should be made not later than June 16th to the Secretary, but as it may be necessary to ballot for places subscriptions should not be sent until the Fellow or Member learns that a seat has been allotted to him.

Tickets for the conversazione at the College and the inaugural meeting at Burlington-gardens (including admission for a lady) may be obtained by Fellows and Members on application to the Secretary.



A short history of the College with eight illustrations has been prepared, and it is proposed to present this to guests invited to the centenary celebrations.

THE JOHNSON HOSPITAL AT SPALDING.—The trustees of this institution have received £5000 from the estate of the late Misses Johnson, of Holyrood House, Spalding. The hospital was built and endowed by the generosity of these ladies.

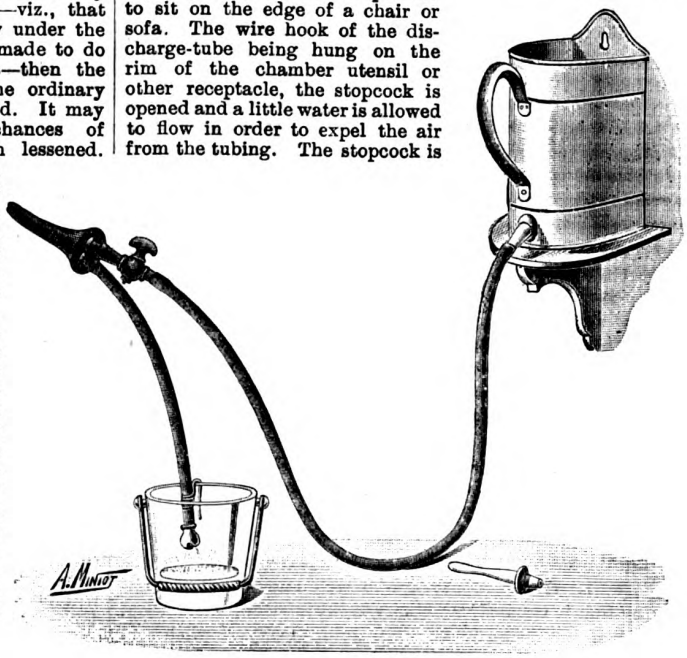
New Inventions.

TONSIL CLAMP.

THIS instrument has been devised by me as a means whereby we may be secure against the hæmorrhage which too frequently occurs in ordinary cases and which is so great a source of alarm to the patient. Much more important is the service which it renders when the operation has to be done upon a young subject under chloroform. When it is understood that with the aid of this clamp the tonsils can be removed with the loss of scarcely a drop of blood its advantages will be readily acknowledged. But a further merit is that it can be applied so as to permit the removal of exactly the amount of tissue desired. If Sir Henry Thompson's postulate be granted—viz., that an instrument should be entirely under the control of an artistic hand and made to do exactly what the surgeon desires—then the superiority of this clamp over the ordinary guillotine must also be conceded. It may also be claimed that the chances of secondary hæmorrhage are much lessened. The instrument in general form resembles the guillotine, but what corresponds to the blade and which is figured A in the cut, has instead of a cutting edge a somewhat broad and serrated border. When the instrument is in action this border presses the tonsillar tissue, which it constricts, against a similarly serrated surface on the concavity of the ring B. After the fashion of the lithotrite the instrument has a male blade D and a female blade E. On bringing the former home upon the part where constriction is desired the button C throws the screw F into gear, so that as much pressure as is desired can be effected. The lump of adenoid tissue can now be shaved off with a blunt-point bistoury. The instrument is made by Messrs. Arnold and Sons, West Smithfield, London.

D. W. AITKEN, M.B., C.M. Edin.

Packington-street, Islington, N.



A POCKET SPITTOON.

THE sputum of sufferers from phthisis being the most active agent in the propagation of the disease, all phthisical patients ought to be provided with some means of guarding against their sputum becoming a source of danger to others. The essential precaution is to prevent the sputum from becoming dry and mixing with dust which is everywhere present, so that the tubercle bacilli are carried up with it and float in the atmosphere. One of the appliances for accomplishing this object is shown in the illustration. It is a bottle of blue glass, made all in one piece, having a funnel-shaped neck and a total height of four inches. It is provided with an easily fitting nickel-plated lid, and from its size and shape may be conveniently carried in the pocket with very little risk of the contents escaping. The price is 1*s.* 6*d.* and the maker is Mr. G. T. W. Newsholme, pharmaceutical chemist, High-street, Sheffield. The contents are disposed of by being thrown on a fire or mixed with a disinfectant and emptied into a water-closet, after which the bottle is thoroughly cleansed.

THE ONAH VAGINAL DOUCHE.

MOST of the many methods that have been devised for the giving of vaginal injections are open to the objection that either the bed-clothes or the patient's under-garments are liable to be wetted during the process, and this in the case of certain metallic solutions and astringent lotions has the further disadvantage of causing indelible stains. To meet this difficulty the Onah douche has a separate tube for the discharge of the used liquid, so that it can be employed without danger of wetting the clothes, especially as the enlarged end of the nozzle prevents any liquid escaping round its base. The douche-can being placed on a high shelf or hung on a nail, the water is supplied under pressure which tends to obliterate the folds of the vagina and causes a constant renewal of fluid round the nozzle. During the injection it is best for the patient to sit on the edge of a chair or sofa. The wire hook of the discharge-tube being hung on the rim of the chamber utensil or other receptacle, the stopcock is opened and a little water is allowed to flow in order to expel the air from the tubing. The stopcock is then closed, the nozzle is inserted in the vagina curving upwards, and the stopcock opened. The can holds two quarts. The instrument can be obtained through any dealer in articles of its kind. For the giving of enemata a bone rectal pipe is supplied fitting into the same stopcock as the detachable vaginal nozzle.

"PORTIA" COMBINED STOCKING SUSPENDER AND SHOULDER SUPPORT.

THE stocking suspender represented in the illustration is made of elastic webbing three quarters of an inch wide, one portion of which is formed into two loops passing over the shoulders and meeting in the middle of the back where it is fastened by means of a crossing buckle. The stockings are held up by two lengths of the same webbing stitched one to each loop and provided with buckles which permit of adjustment according to the height of the wearer. It is intended to be worn between the underclothing and corset and can be easily adapted to any figure. The stockings are suspended directly from the shoulders and by use of this article the circulation is not impeded as it is by garters. In some of the patterns there are rubber clips to make them especially suitable for use with thin silk stockings. The makers are the "Portia" Company, 202, Romany-road, West Norwood, Surrey.

THE LANCET.

LONDON: SATURDAY, JUNE 9, 1900.

AMONG the multifarious questions which occupied the time of the General Medical Council at its last session few were of more importance than that of legislation in Italy and England respectively upon the rights of reciprocal practice. The conditions of medical practice at home and the regulations for acquiring the right to medical registration are pretty well defined, and there is not likely to be any great departure from them as far as domestic legislation is concerned. But we enter another region altogether when we contemplate the British practitioner abroad, and try to lay down laws or principles of law for the acceptance of other States, which shall give our practitioners the right to practise in alien lands and which shall concede to foreigners a similar right in our own country. And this is the region into which the Council has had to enter *nolens volens*, inasmuch as the Privy Council have promised to consider the question of recognising in this country Italian medical degrees.

We are called an insular people. But there are few people in the world less so than we are. Our travellers explore every country, and in ever-increasing numbers reside in other lands. Our commerce permeates everywhere, our ships carry for the world. To be just to ourselves it must also be admitted that we entertain strangers. We have in London, to look at another aspect of the matter, more Germans than there are in some large German towns, more Scotsmen than there are in Edinburgh, more Welshmen than there are in Cardiff, and more Jews than there are in Jerusalem. The men of Britain are at home on every continent, in every capital, and on every sea. They are said at the present moment to be unpopular. That is a passing phase. Complaint is soon heard if they withdraw their custom or withhold their presence from any country, and provision is soon made to conciliate and attract them. In short, with all our insularity we are the most ubiquitous people in the world. It is due to this quality that the General Medical Council has had to face the question of the exclusiveness of our medical laws. The discussion has been forced upon them and upon the Privy Council by men on our own Medical Register. They invade foreign countries, they follow their wealthy compatriots into France, Italy, and Switzerland, and they do so in such numbers and with such success as to excite the jealousy of the practitioners in these countries and to provoke the passing of protective measures against them. Other countries have had their attention aroused to the subject of the exclusive tendency of medical legislation—Germany and Russia, to wit—and have entered into communication with our own Government on the subject. So far we have been as exclusive in our medical laws as other nations if we have not been desirous of inflicting any penalties for encroachment. We have not opened our doors for the free admission to the privileges of the profession in Great Britain to foreign medical practitioners. We have not legalised their position, and it may be admitted that we have not, even in London, recognised the right of foreigners, except in the case of "any hospital established exclusively for the relief of foreigners in sickness," to have medical practitioners of their own nationality. But we have not been cruel in our exclusiveness. We have seldom or never threatened with penalties any practising physician or surgeon possessed of reputable foreign diplomas; we have actually provided by legislation for foreigners in their own hospitals being treated by their own countrymen without English qualifications; and we passed a law 14 years ago, the Medical Act of 1886, for the recognition of foreign diplomas under reasonable conditions. This measure it is now proposed by the Government to apply to Italy, and out of their expressed intention arose the debate on the subject which is reported in our columns.

A great feature of the Act of 1886 was the proposal to enter into reasonable and just relations with other countries as regards the recognition of their medical diplomas; and, in order to do this, it was left to the Privy Council to determine when this law should be acted on in relation to any given country. The medical profession would perhaps have liked the Act better if it had left the determining function in the hands of the General Medical Council. To the latter body, however, is intrusted the decision as to whether the diploma of any given foreign institution furnishes a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery. The General Medical Council has done well to pass a resolution pointing out to the Government that the concession contemplated by the Italian Government is not equal to the concession which we should have to make to them. We think that our medical brethren in Italy were a little too ready to express satisfaction with the imperfect privilege of attending only their own countrymen, whereas the Act of 1886 would concede to Italians here the full rights of practice. Many will be disposed to agree with Sir JOHN BATTY TUKE that after all the most satisfactory solution of the difficulty would be the acquisition by English practitioners of the qualification of the countries in which they wish to practise. This course has already to a certain extent been adopted in those countries where no other is open, for there are not a few of our countrymen practising in France who have added to their English qualifications the distinguished degree of M.D. Paris. If, however, the Government is bent on "reciprocity" there must be *real reciprocity* and not a mere travesty of the principle of enjoyment of equal rights. Whatever be the departure, if any, decided upon, all will agree that practitioners already established in a foreign country cannot be disturbed in their vocation without a risk of the infliction of considerable hardship upon them being incurred.

THE second reading of a short Bill introduced by the Government in the House of Commons to amend the Housing of the Working Classes Act of 1890 recently produced an interesting discussion on the problem of how to provide the poor in large towns with wholesome dwellings. By Part III. of the above Act local authorities may provide lodging-houses, as the Act calls them, the term including separate

cottages, for the working classes in their district, and the new measure enables councils, other than rural district councils, to go outside the limits of their own locality in order to acquire by purchase suitable sites or houses for this purpose. The present Bill has now been read a second time and would probably have passed this stage of its progress towards maturity almost unobserved but for an amendment moved by Mr. ROBSON, Q.C., which sought to import powers into it to compel railway companies to provide train accommodation for the people who, when the Bill becomes law, may be expected to be housed at a distance from their work. This amendment was ultimately dropped, it being apparently conceded that the existing law was strong enough to meet the requirements of the situation, and that the railway companies had hitherto gone as far as could reasonably be expected of them.

We can well understand that the London County Council, for instance, may be enabled with advantage to purchase land outside the costly area in which it holds sway, in order to build houses which, instead of being of the big block order of architecture, may provide pleasanter and more healthy homes in the form of separate cottages at a smaller total cost. At the same time, no one can deny that to compel railway companies to provide trains in order to further such schemes, and to provide them at a possible loss, is to lay upon the railway companies a large share of the burden of re-housing the working poor, and this view seems to have been adopted by the House of Commons in rejecting a private member's Bill to increase the facilities of railway travelling for workmen living in the suburbs, just at the time when Mr. ROBSON'S amendment was also before it. The debate upon Mr. ROBSON'S amendment produced from Mr. A. J. BALFOUR an interesting pronouncement of the right honourable gentleman's views upon the future conditions of travelling which the coming generation should preserve in order to be able to criticise him in the future in the character of a prophet. "I believe," said Mr. BALFOUR, "we are on the eve of an immense social reform, of an immense augmentation of the means of communication. I believe that electrical traction and other forms of traction are going to play a far larger part in the solution of this difficulty than any of the strange schemes which I have analysed to the best of my ability for the benefit of the House. I sometimes dream—perhaps it is only a dream—that in addition to railways and tramways we may see great highways constructed for rapid motor traffic, which would have the immense advantage, could it be practicable, of taking the workmen from door to door, which no tramway or railway would do." Let us hope that Mr. BALFOUR may be correct in his vaticination; still at the same time let us remember that such a state of affairs as he predicts will ameliorate the condition of the artisan and of the labouring man in regular work, but will hardly touch the vast army of the poor who fail to come under either of these classes, although they have nothing save their own fitful exertions in one direction or another for their support. We can scarcely picture the sweated sempstress or the foreign refugees from Poland, who toil and starve in overcrowded slums within half an hour's trudge from the place where their ill-rewarded work is given out to them, dwelling in a more or less airy suburb, and coming to town in a workman's train or a workman's motor-car to fetch away the materials on which they are to labour unceasingly for the next 16 hours. We can hardly even picture the coster, as a class, travelling in similar wise to take his donkey and cart or his barrow out of a livery stable and proceed to commence his day's operations at the early market where his stock-in-trade is purchased. The seconder of Mr. ROBSON'S amendment, Mr. STEADMAN, M.P., L.C.C., spoke of 400,000 human beings in the county of London living in one-room tenements, 30,000 living six in a room, and 3000 eight in a room. It is not easy to believe that many of these will benefit greatly either by the Government Bill when it becomes law or would have been greatly affected had the amendment in question been passed. Members of this class, if they are ever to live in healthy conditions at all, will still have to live near where their work, such as it is, lies, or where they may most easily seek it. The building of houses for them by the London County Council so as not to form a perpetual drain upon the rates of London seems well-nigh impossible, whatever may be done by private enterprise and philanthropy. The high value of land in all central localities is the main obstacle. It has been the cause of the Bill we have referred to, and it was more than suggested during the debate that the price is inordinately enhanced where the County Council buys under compulsory powers, slum dwellings being then paid for as if they were substantial buildings earning honest profits for their owners.

Under the Housing of the Working Classes Act of 1890, when the arbitrator fixes the compensation payable under an improvement scheme in respect of premises situate within an unhealthy area, he is bound to receive evidence as to the premises being used for illegal purposes and as to overcrowding or defective sanitation. He is then to base his compensation on the rental obtainable if the premises were used for legal purposes and without overcrowding, while their value if in a sanitary condition is to be computed and the amount necessary to put them in such a condition deducted. On the other hand, if the premises are incapable of being made habitable their value is to be the value of the land and the materials on it only. It will be seen from this that, if unhealthy areas are rigorously treated as such, the compensation need not be excessive and, indeed, cannot be so without gross mismanagement. It is, in our view, wiser to urge the strict enforcement of the existing law against the slum-owner, using the law to the full to provide better dwellings to replace those forcibly closed, than to stand idle while hoping for some better or vaster scheme to be devised, such as a tribunal in the nature of a land court to fix the rents of workmen's dwellings. This particular proposal has features which appear to commend it at first sight, but for the reasons given by Mr. BALFOUR to the House of Commons, if for no other, it hardly seems likely to take a definite form at present.

A TREATISE by the renowned ancient physician, GALEN, concerning the foods best adapted for preventing or reducing obesity, entitled in the Latin "De victu attenuante Liber," has now for the first time been edited in the original Greek by Dr. C. KALBFLEISCH of Fribourg. It is dedicated to his

confrère, Dr. J. ILBERG of Leipsic, and is published by TEUBNER of that city. This is the last work of GALEN catalogued at the British Museum, and, so far as we can discover, the editor's statement that its Greek text has never before been printed is undeniable. That its attribution to GALEN is correct is apparently confirmed by the fact that it is quoted and referred to by such classical medical authors as AËTIUS, whose date is disputed, although it was probably about the end of the fifth or the commencement of the sixth century, by an anonymous author who addressed a treatise, "De Medicinâ," to CONSTANTINUS POGONATUS (668 to 685), and by MICHAEL PSELLUS, a philosophical writer of the eleventh century. Besides these, ORIBASIUS, who according to the best authorities was born at Pergamos, in Mysia, the birthplace of GALEN, in his work "De Victûs Ratione" made large use of GALEN'S treatise; and HONEIN-IBN-ISHAK, an Arabian physician of the ninth century, is authoritatively asserted to have made an Arabic translation of it. Dr. KALBFLEISCH, in his elaborate preface, examines at considerable length the origin and nature of the Latin versions in existing editions of GALEN, and particularly states that four pages are wanting in all of them which refer to certain Asiatic wines, of which GALEN says, ἀλλα γάρ οὗτοι ἐναντιώτατοι τῇδε τῃ διαιτῃ (but these are most opposed to this kind of regimen), evidently implying that the western translator into Latin thought it worthless to trouble himself or his readers about Oriental liqueurs. Dr. KALBFLEISCH then proceeds to show whence he obtained the codex of his Greek text—viz., through the researches of a certain MINOIDES MYNAS, whom he amusingly describes as "vanus homo et impurus, sed idem in codicibus pretiosis investigandis prosperâ fortunâ adjutus." This worthy, about 1840, returned from the East with manuscripts in the original Greek of this and other writings, and after they had been temporarily deposited with Messrs. ABBOTT, bankers, at Salonica, they were purchased by various libraries, this treatise finding its home in the Bibliothèque Nationale. With true German diligence Dr. KALBFLEISCH minutely compares the Latin versions—particularly that made by NICHOLAS RHEGINUS for the edification of ROBERT of Sicily in the fourteenth century—with that made by MARTIN GREGORY, medical professor at Paris, about 1580, though his version, he believes, is only a paraphrase of that of NICHOLAS. Without going into the complex details and many referential figures of this introduction to the Greek text we will briefly analyse the contents of the text itself. The entire work is a sort of scientific anticipation of the notorious "Banting" treatment of some 40 years ago. The author deprecates the use of drugs for the dissipation and destruction of fatty particles in the system, stating that in his experience he has known of many cases of renal and rheumatic complaints cured or alleviated by use of a proper diet. Chapters I. to VII. treat of herbs and seeds which are calculated to produce the required result. GALEN here recommends leeks, onions, mustard, and nasturtiums as beneficial, also watercress and pennyroyal, though these are better taken green than dry, since when dry they in a measure become drugs. Generally speaking, herbs and vegetables grown upon hills are stronger than those grown in the valleys. Chapter VIII. describes the birds and fishes which are suited to his regimen, and recommends fishes which haunt rocks and birds frequenting mountains, saying that aquatic birds are fat-producers. All wild birds and game are less fattening than those which are brought up domestically. In Chapter IX. GALEN says that beetroot is not to be taken, neither the roots of vegetables which are round. Chapter X. treats of fruits, saying that mulberries are good as a laxative. Peaches should be eaten rather in a soft pulpy state than in a hard one, but these fruits must not be eaten εἰς κόρον—i.e., to excess. Persian and Armenian melons should also be avoided, but the Seric, or Chinese, melon may be eaten. In Chapter XI. GALEN recommends vegetables which have been preserved in vinegar or brine; and in Chapter XII. he discourses of the effects of honey, milk, and various wines, stating that sweet wines produce thickness of blood. It would be interesting to the profession if a competent medical scholar would translate this treatise into English, but this could only adequately be done by one who had made a considerable study of GALEN'S works in the original Greek.

Annotations.

"Ne quid nimis."

WOUNDS CAUSED BY MODERN SMALL-ARM PROJECTILES IN THE CUBAN CAMPAIGN.

SIR WILLIAM MAC CORMAC in his address at the meeting of the Royal Medical and Chirurgical Society on May 22nd[1] referred to a valuable communication made by Professor Nancrede of the University of Michigan to the last meeting of the American Surgical Association. Professor Nancrede's paper, so opportune at the present time, is published in vol. xvii. of the Transactions of the American Surgical Association and deals with the effects of modern small-arm projectiles, as shown by the wounded of the fifth army corps during the campaign resulting in the capture of Santiago de Cuba. Professor Nancrede gives the outcome of some 1500 cases of gunshot wounds which he had himself observed during the war in Cuba in 1898, about 1400 of which were cared for at the hospital with which he was connected. His present attitude in regard to many of the questions discussed should, as he rightly urges, carry greater weight because it is opposed to that which he formerly held as the result of what his past experience had taught him. The trivial, almost incised, character of most flesh wounds might have been anticipated, because with such immense velocity, if little resistance is experienced, the missile will retain nearly all its energy, practically imparting none to the tissues and the devitalisation of the ball-track is consequently reduced to a minimum. He considers that the greatest advance in military surgery on the battlefield in recent times is the "first-aid" packet and the greatest boon conferred on the wounded soldier has been asepsis and antisepsis, because in the majority of instances rendering his injuries so painless and their complications so slight that even anæsthetics no longer occupy the chief place as a blessing to the wounded because no longer needed. Professor Nancrede is emphatically in favour of prompt and energetic antisepsis, too, in order to minimise the evils resulting from infection. The ubiquitous pyogenic organisms

[1] THE LANCET, May 26th, 1900, p. 1485.

present in and upon a patient's skin immediately surrounding the wound would readily find lodgment in the wound unless at once inhibited by contact with an efficient germicide. The removal of limbs for extensive fracturing of long bones in the Cuban campaign was almost unknown. Exploration with extraction of splinters was sometimes done, but antiseptic occlusion was the rule and was followed by the best results just so long as infection was avoided. Joint wounds were likewise usually successfully treated by antiseptic occlusion with such fixation as was available. According to the official report, "more than a score of gunshot wounds of the knee-joint were thus treated with the happiest results." Antiseptic occlusion also proved the best treatment for most of the thoracic and abdominal injuries. Professor Nancrede was informed that of the perforating ball wounds of the abdomen all that were operated upon proved fatal, while he saw a number which were recovered from without operative intervention, antiseptic occlusion being relied upon.

MR. BARTLEY, M.P., AND THE SHOREDITCH VESTRY.

THE *Times* of May 28th contained a letter from the clerk of the Shoreditch Vestry written under instructions given by the Public Health Committee of that body. This official document deals with a speech recently made in the House of Commons by Mr. Bartley, the member for North Islington, in the course of a debate on the Bill for the Housing of the Working-classes. The Shoreditch Vestry contend that a serious and unmerited reflection has been cast on metropolitan authorities generally and on themselves in particular by Mr. Bartley's remarks. The paragraph in his speech to which they take special exception is as follows:—

"Another matter which hampered progress was the difficulty of satisfying local authorities. Within his own knowledge there was a case where everything that was possible was done in making good sanitary arrangements and providing an excellent water-supply to a block of houses. The local authority stepped in a few years afterwards and condemned the whole arrangement, which had to be altered at the cost of £500. Three years after that the same sanitary authority and the same inspector insisted on reinstating all the appliances which had been removed, and that was done at a cost of £300."

The Shoreditch Vestry believe that the dwellings referred to are within their own area and are the property of Mr. Bartley himself. On this assumption they quote from a report made in the year 1892 by their chief sanitary inspector on the dwellings to which they believe Mr. Bartley refers:—

"It was found that the various water-closets were fitted with tilting water-pans and iron containers—all in an extremely foul condition. In several instances the water-pans were gone and the emanations of the foul containers rose freely into the closets. The cisterns supplying the people living on the first, second, and third floors were found in the water-closets, close up to the ceilings, so that an examination of the state of the cisterns could only be made by removing the floor-boards of the water-closet overhead. This having been done the cisterns were found to be in a very filthy condition and there was abundant evidence that the water was fouled by excrementitious matters overflowing the closet pans. Against that contingency it did not appear that the builder or even the architect had thought it necessary to take any precautions whatever."

The clerk of the Shoreditch Vestry goes on to state that the cisterns were removed and each water-closet was fitted up "in a superior manner." Three years later the pressure in the mains of the East London Waterworks Company was insufficient to supply the upper floors of the tenements during the day time, and Mr. Bartley was required under a magistrate's order to supply storage cisterns in the roof. It is not stated who applied for the magistrate's order for the reinstatement of cisterns, but it is stated that the order was made under the "Public Health Acts." We should be glad to know under what section of what Act it has been held by a magistrate that a landlord can be compelled to supply a cistern in an area in which a metropolitan water company is under a statutory obligation to give a continuous supply of water. The Shoreditch vestry clerk remarks: "That the East London Water Company failed in giving a proper water-supply to the dwellings was not the fault of the sanitary authority who, during the recent water famines, have by every means in their power endeavoured to get Parliament to keep this defaulting monopolist company up to its duties to the public." It must be pointed out to the Shoreditch Vestry that Parliament has delegated the supervision of the water-supply to the vestries and to the County Council, and that these bodies are empowered by Acts of Parliament to insist that a constant supply of water shall be given to London water consumers. With a constant water service cisterns are not needed. The Shoreditch vestry clerk ends his letter by saying that two Royal Commissions and a Local Government Board inquiry have thwarted the efforts of the local authorities of London. It is hardly necessary for us to remind our readers that Lord Llandaff, on the contrary, severely and repeatedly blamed the local authorities of London for not availing themselves of their statutory privileges in dealing with peccant water companies.

SEATS FOR PARIS SHOP ASSISTANTS.

DR. FOVEAU DE COURMELLES is seeking to move the Société Française d'Hygiène so that an agitation may be organised having for its purpose to obtain seats for shop assistants. He declares that in the four leading drapery establishments of Paris there are no less than 6000 women whose health is gravely compromised by the conditions under which they work. They are condemned to sterility, or to dangerous and very difficult accouchements, or to uterine diseases, &c. But the men also suffer in common with the women from varicose veins and from a form of albuminuria which Stirling qualified as "postural albuminuria." Dr. de Courmelles says that in Paris the "demoiselle de magasin" has to be at her post at eight in the morning. She must then proceed to the sixth floor to renew her stock from the store-room. After this she must go to the control and labeling offices which are generally in a second basement. These journeys have to be repeated several times and thus it is necessary to climb 600 or 800 steps before the arrival of the customers. At breakfast time, from 11 to 12.30 A.M., the men are able to go out for half an hour to smoke and enjoy fresher air, but it would not be considered respectable for young girls to stroll about the streets alone. The vitiated air that is breathed in the large and crowded establishments renders the fatigue endured much more injurious and it must not be forgotten that the influenza epidemic began in one of these Parisian establishments shortly after the last Universal Exhibition held in 1889. The women also who are employed for trying on dresses and mantles, &c., depend on the elegance of their figures for their livelihood. Consequently they deprive themselves of some of the food they need for fear of becoming too stout, and then there is, of course, the temptation of lacing too tightly. The hope, so natural in women, of happy and healthy maternity must be abandoned unless they are in a position to leave their work altogether. Many are obliged to remain and are therefore prematurely aged and invalided. When late in the evening the great shop is shut the work is not over. All the goods have to be carefully folded up and put in their proper places. Then the accounts of the sales effected must be added up and the report thereon prepared. When this has been accomplished it is often necessary to wait a long time before it can be checked by the chief of the department and thus it is past 9 P.M.

before the shop assistants are able to go home to eat and above all to sit down. Under these circumstances, there is even more need in France of a Seats for Shop Assistants Bill than in England, where the hours of labour are not so long and where all shops are closed on Sundays and most shops close at 2 P.M. on one of the week-days. As in France so much is attempted by the State and by private charity to preserve infant life and to encourage maternity it is somewhat surprising that the need of providing seats for shop assistants, especially the women, is not better appreciated, and that comparatively little has been said or done in this direction.

THE SOLICITORSHIP OF THE GENERAL MEDICAL COUNCIL.

WE have already announced the resignation of Mr. Farrer who for many years has acted as the solicitor of the General Medical Council, and who will be remembered with respect and pleasure by its members. The Council has elected as its standing solicitor in his place Mr. W. H. Winterbotham, who is also official solicitor to the Court of Appeal. It is understood that the work of the Council as respects law and police-courts will be done by another solicitor to be approved by the Council.

DINNER TO SIR WILLIAM T. GAIRDNER.

IN THE LANCET of March 31st (p. 956) we gave a short outline of the eloquent speech in which Sir William Gairdner intimated to his class in the University of Glasgow his decision to resign his professorship of the Practice of Physic. We have now pleasure in announcing that his very numerous friends in the University and among the medical profession in the West of Scotland will entertain him at dinner in the Windsor Hotel, Glasgow, on Tuesday, June 19th. In view of the importance of the occasion the arrangements are being made by an influential committee, which includes the Rev. R. Herbert Story, Principal of the University, and Sir Hector Cameron, President of the Faculty of Physicians and Surgeons of Glasgow. Tickets, 21*s.* each, can be obtained from Messrs. James MacLehose and Sons, 61, St. Vincent-street, Glasgow, and the committee state that early application for tickets is necessary, as the number is limited, and no application can be entertained after June 14th.

THE DEVELOPMENT OF THE CRANIUM.

A CAREFUL study of the development of the primordial cranium has recently been made by an Italian physician, Dr. Giuseppe Levi of Florence, and the results of his researches, published in the *Archiv für Mikroskopische Anatomie*, Band lv., p. 341, 1900, are contained in the following propositions. The first rudiments of the primordial cartilaginous cranium in man occur in the form of isolated groups of closely compressed connective-tissue cells in looser tissue than that which forms the membranous primordial cranium. There is a certain homology between these aggregations of cell groups and those of the future bone. There is no homology between these rudiments of the skull of man and those described in mammals as parachordals and trabeculæ. The rudiments in question, even after their conversion into cartilage, preserve their identity for some time by the possession of a perichondrial layer. It is only just before the chondrocranium has attained its highest development that all the rudiments coalesce and then only does the chondrocranium form one continuous whole. The rudiments formed by connective tissue are not all formed coincidently; that of the occipital bone is the earliest, then follow those of the sphenoid and of the auditory capsules, and the last to appear is that of the ethmoid. The differentiation of the several rudiments does not progress with equal rapidity—as a general rule it advances with the greatest rapidity in the latest formed parts and presents in each case characteristic features; thus in the occipital region it takes place quickly and almost contemporaneously throughout its whole extent, whilst in other instances it commences at a definite spot by a kind of cartilaginous nucleus and spreads uniformly outwards. The enlargement of the rudiments is rapid at first but extremely slow afterwards. The development of the occipital region presents a great similarity to that of the vertebral column. In particular the histological features of the formation of cartilage are different from those of all other segments of the skull and are identical with those of the vertebral column. Moreover, there is one distinct rudiment of a vertebra—that is the occipital—which has a symmetrical origin, and further forwards there are parts of an indeterminate number of vertebræ. The occipital region, like the vertebral column in the first stages of its development, is in connexion with the chorda, but as the cartilage develops it becomes distinct from the chorda. All this supports the statement made by Froriep that the occipital region represents the true spinal segment of the skull in man. The symmetrical rudiments of the body of the occipital vertebra become the condyles of the occipital, the unsegmented portion represents the portio basilaris, and the lateral portion of the arch of the occipital vertebra the processus jugularis. The form of the rudiments antecedent to the appearance of cartilage does not always correspond to that of the cartilage when fully formed since parts of the rudiments undergo absorption. The chief changes that occur, however, are those consequent on the remarkable alteration of position of the occipital and sphenoid rudiments. The floor of the sella Turcica is the only segment of the whole skull which preserves its original position throughout the process of development.

A CURIOUS THEORY OF PLAGUE.

THERE should be no difficulty in preventing the spread of plague according to the remarkable theory put forward by a correspondent in a pamphlet recently published in India. In this pamphlet, a copy of which we have recently received, the author sums up his view in a final paragraph as follows: "I humbly state that the more close the investigations and experiments the more fairly we expect to be convinced of the fact (*sic*) that plague is nothing but slow and gradual poisoning of carbonic acid gas." According to this view we should expect plague to be a chronic disease in this country, having as a starting point mineral water works or breweries, for in these places there is constantly a large proportion of carbon dioxide in the air. As a matter of fact the health of the operatives in these industries, in spite of a high proportion of carbonic acid in the air at times, is good. Carbon dioxide is, of course, a poisonous gas, but only when present in great excess. As Dr. J. S. Haldane has shown air may contain from 3 per cent. or 4 per cent. of carbonic acid gas without producing any serious distress. The author of the pamphlet referred to suggests as a plan of prevention the placing of all patients on the second floor or third floor of the building, for he remarks that carbonic acid gas is a heavy gas and accumulates on the ground floor and it is on the ground floor where the disease flourishes. If there were no such thing as a law of the diffusion of gases human life would have ceased to be long ago, for there is sufficient carbonic acid in the air to form a layer over the surface of the earth of the dimensions of an ocean, and in such an ocean life would be, of course, impossible. It is a pity that the author's simplicity of idea as to the origin of plague is not true, for such a simple *fons et origo mali* could easily be removed. When, however, he speaks of over-crowding, ill-ventilation, and

dirty environment as factors in the etiology of the disease he is right, but to say that these conditions indicate nothing but the accumulation of a large quantity of carbonic acid gas and insufficient quantity of oxygen is to ignore the teachings of modern research and to manifest a lamentable ignorance of the nature of infection.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the list of candidates for vacancies upon the Council should be added the names of Mr. W. H. Bennett, surgeon to St. George's Hospital, and Mr. R. Clement Lucas, surgeon to Guy's Hospital. The full list will be found on p. 1674.

THE INTERNATIONAL CONGRESS OF MEDICINE.

IN answer to many inquiries which have been addressed to it, it is announced by the Executive Committee of the Thirteenth International Congress of Medicine that it has decided that dentists who are not doctors of medicine, but who nevertheless are registered or possess a *diplôme d'état*, either French or foreign, can register themselves as members of the Congress in the Section of Stomatology. Names must be sent to the Bureaux of the Congress, the address of which is 21, rue de l'École de Médecine, Paris.

LOSS OF MEMORY AND OF SENSE OF PERSONAL IDENTITY.

CASES of this sort, though decidedly uncommon in occurrence, are of considerable medical and legal interest. The record of a specially interesting case is published in the *Philadelphia Medical Journal* (May 19th, 1900) and recalls the occurrence of a similar case recently at Cambridge where a young undergraduate disappeared from his quarters and was not heard of for several days till he was discovered staying at an inn in the country some distance from Cambridge. He seemed to have had no recollection of leaving his rooms in Cambridge or of any of the incidents subsequent to that event and until his arrival at the inn, except that he was feeling tired and fatigued and that his boots and clothes were wayworn and dusty. The undergraduate was a youth subject occasionally to epileptic fits at infrequent intervals, and it appears that after such a fit he lost his memory and his sense of personal identity and wandered about until he came to the inn where, wearied and worn out, he took lodgings. He had lost all recollection of his former life and condition and stayed in the inn for some days. Then a second fit occurred after which the memory of his former self returned and he was able to realise his position and find his way back to the University. The case reported in the *Philadelphia Medical Journal* is that of a law student, aged 19 years, living in New York, who suddenly lost his memory and sense of personal identity and found himself wandering in the streets of what he considered a strange city. He was so perplexed that he asked people in the street if they could tell him who he was and went to the libraries and hotels to search in the newspapers for stories of missing persons in order that he might get some clue to his identity. He lived at a hotel and after spending five days in fruitless wanderings and inquiries he finally entered a police station and inquired of the sergeant on duty whether he could inform him in what city he was and requested that search might be made in the record of missing persons. When this was done it was found that there was a description closely tallying with his appearance. A detective was sent with the youth to the address given in the description, where the wanderer was received with great joy by his mother and sisters. To their great surprise, however, he thanked them very politely, but assured them that he did not know them or the place. The mother told the police that he was a somnambulist and had left home previously under similar conditions. In the youth's pocket there was found a diary in which he had entered the details of his daily experience since the time he left home and forgot who or where he was. "His physicians state that his attack of amnesia is gradually passing off, and that while he shows memory of other events in his past life any reference to himself seems to be the signal for another lapse of his memory." The import of cases such as the above is evident both from a medical and medico-legal standpoint, and it is interesting to note their affinities with such neuropathic conditions as epilepsy and somnambulism.

UNIVERSITY OF LONDON: THE ROGERS PRIZE.

AT a meeting of the Senate of the University of London, held on March 28th, 1900, it was resolved that one sum of £100 be offered as the Rogers Prize open for competition to all the members of the medical profession in Great Britain and Ireland for an essay under the following regulation as to the subject and conditions thereof, namely: an essay by any member of the medical profession in Great Britain and Ireland upon the Production of Immunity in Specific Infective Diseases; generally, and with particular reference to any one disease on which the writer of the essay has made original investigations. The essay is to be sent to the Registrar, University of London, South Kensington, S.W., on or before June 1st, 1901.

INTERMENSTRUAL DYSMENORRHŒA.

THE *Boston Medical and Surgical Journal* of April 19th contains an important paper by Dr. M. Storer on this rare and interesting affection. His observations lead him to conclude that intermenstrual dysmenorrhœa is not so rare as has been asserted: he had found it last summer 18 times in 400 "suitable cases" in which he inquired as to its existence. Analysis of 20 cases under his care and of 25 collected from literature led to the following conclusions. As regards regularity the pain in all cases appeared practically every month. In 22 cases it always occurred on a definite day from the beginning of the last menstruation; in 13 there was a variation of two days and in 4 of four days; in 2 with irregular menstruation it occurred on a definite day before the next menstruation. As regards day of appearance from the first day of the previous menstruation, out of 41 cases it came on in from the twelfth to the sixteenth days in 37. As to character, in a large number of cases it was described as paroxysmal, the attacks either coming on at intervals of several hours and lasting from five to 15 minutes or the pain being constant with exacerbations often of the greatest severity and resembling that of labour. As to duration, in 10 it lasted two days; in 9, three; in 8, one; and in 4, four or more. In no case was there a discharge like that of menstruation, but in two cases (one of bleeding fibroids and the other of hæmorrhagic endometritis) there was a slightly sanguineous discharge. Hence the term "intermenstrual dysmenorrhœa" is inapt. On the other hand, a marked increase of leucorrhœa is spoken of in 10 cases, which is evidence of temporary congestion. As to causation, the pain in most of the books is described as ovarian but it is not always so. In one case it disappeared after the removal of a hydrosalpinx; in another, after the uterus was curetted for endometritis; and in a third, stenosis of the internal os was apparently the only lesion. On the other hand, out of 40 cases in which the local condition is stated more or less of an inflammatory condition of the appendages is described in 30 ("ovaritis," 15; "salpingitis," 12; and "hydrosalpinx," three). The exact manner in which the

phenomenon is produced is not known. More or less doubtful explanations, mechanical and neurotic, have been brought forward.

MORTALITY AMONG SEAMEN.

IN the issue of the *Syren*, a paper dealing with mercantile marine matters, for May 30th, appears an article entitled "Deaths on Shipboard" which is particularly interesting from a medical point of view. The Registrar-General of Shipping and Seamen issues monthly mortality returns from which it appears that although the average number of deaths in the British Mercantile Marine is about 300, the returns for March show the very high total of 808. Not all of these deaths, however, actually occurred in March and by far the greater part were due to the heavy gale which swept over the North Sea in the month of February. Some deaths, too, reported in March were due to the hurricane which devastated the Bahamas in August, 1899, and the two together were responsible for the loss of 413 lives by drowning in the case of vessels now reported as "missing." Of the other deaths 26 were due to chest affections and 18 to heart disease. Yellow fever is credited with 11 and malaria with 10 deaths. Falls from aloft killed 10 seamen and 20 met with other fatal accidents. Only one case of death from typhoid fever is reported. The number of deaths due to "chest complaints" is very small and shows that diseases of this kind are due, not so much, as is popularly believed, to cold and wet as to dust and the various other abominations which are found in the atmosphere of great cities. Many forecastles and much sleeping accommodation in the mercantile marine are still far from being what they should be, but there is always plenty of fresh and dust-free air on deck. The tale of deaths from "missing" is, however, a terrible one, and these apparently occurred mainly among fishing craft and coasters. The latter class of vessel is in many cases, we fancy, by no means too well found, and a glance at any wreck chart will show how dangerous are our own coasts to this kind of vessel.

RECOVERY FROM MENINGITIS IN TYPHOID FEVER.

THE following case, described at the meeting of the Société Médicale des Hôpitaux of Paris by M. Troisier, is interesting as an example of recovery from typhoid meningitis. A patient, aged 24 years, had typhoid fever of the adynamic form. The disease ran a regular course and the only peculiarity was the intensity of the headache which began with the prodromal period and its persistence, though in less degree, throughout the whole of the febrile period. The temperature commenced to fall on the twenty-first day, and on the twenty-fourth day, when defervescence was complete, the patient, who had never ceased to suffer from her head, complained of violent headache and photophobia. There were painful contracture of the cervical muscles, which rendered flexion of the head impossible, and repeated vomiting which took place without effort. The pulse was small and irregular and had become slowed from 90 on the previous day to 65. The meningeal streak was well marked. Kernig's sign was absent. These symptoms persisted without fever for four days. The patient was in a state of torpor accompanied by agitation and slight nocturnal delirium. She comprehended what was said to her, but answered slowly and had an absent air. On the twenty-ninth day the vomiting ceased and all the other symptoms improved, the headache and stupor diminished, the stiffness of the neck disappeared, and the pulse became regular. On the thirty-seventh day phlebitis with marked œdema of the whole left lower limb appeared. On the following day the meningeal symptoms had completely disappeared. In about three weeks the phlebitis of the left lower limb had passed away, when the right was attacked, but less severely. Complete recovery ensued. M. Troisier insisted that in spite of the recovery the intensity of the symptoms established the diagnosis of meningitis which was produced by the typhoid bacillus or by some secondary infection. He quoted M. Dupré who has stated in the "Manuel de Médecine de Debove-Achard" that infectious meningitis might become cured. The phlebitis, he thought, was a mere coincidence and but another manifestation of typhoid infection.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

THE members of the Yorkshire branch of the above society held their annual dinner on May 31st at the Hôtel Métropole, Leeds. Mr. T. B. Fairclough of Mirfield, the President of the branch, was in the chair, and among the guests was Professor Clifford Allbutt who proposed the toast of "Our Society." He referred to the exceedingly valuable results which had been accomplished within his own recollection by the labours of medical officers of health and by the science of preventive medicine. Malaria, plague, and typhus fever were extremely rare or even absent in this country and he thought that in time tuberculosis would become as rare as typhus fever was now. But perhaps the most interesting portion of the speech of the Regius Professor of Medicine of the University of Cambridge was that passage wherein he referred to cancer. He urged his hearers to lose no opportunity of tracing out the distribution of cancer and said that when he reflected what had been done within the lifetime of one man towards the extinction of typhus fever and that plague and malaria had been absolutely abolished in this country he was confident in thinking that even cancer might be wiped off the slate. They did not know much about cancer, but the weight of evidence was on the side of its being an infectious disease. Optimism in medicine is undoubtedly a thing to be cultivated, but we fear that it may be long before cancer is "wiped off the slate." Still, the labours of Mr. Alfred Haviland and Mr. D'Arcy Power with regard to the geographical feature of cancer distribution, to say nothing of the pathological and physiological researches of many other workers, even if no definite results have as yet been arrived at, are at any rate an earnest that the problem is being steadily attacked.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

THE first annual dinner of this institution was held at the Trocadéro Restaurant on May 31st. The Right Hon. Lord Strathcona and Mount Royal was in the chair and the large number present testified to the interest which is extended to the youngest of London's medical colleges. The gathering was a most successful one and the committee responsible for the proceedings may congratulate themselves on the results of their labours. The Royal toasts were received with the enthusiasm which characterises all references to the Queen and all members of the Royal Family at the present time. Sir Henry Burdett proposed "The Imperial Forces," referring more particularly to the services rendered by the chairman and other representatives of the colonies to the mother country. Surgeon-Captain Kingscote and the Hon. R. H. Lyttelton responded, the latter thanking those present for the manner in which they had received the mention of the name of his brother, General Lyttelton, now serving in South Africa. Lord Strathcona, in proposing the principal toast, "The Medical Graduates' College and Polyclinic," briefly explained the objects of the institution, the main one being to enable qualified men who had left the hospitals and entered on the practice of their profession to keep themselves

abreast with the advance of medical knowledge. Sir William Broadbent, President of the institution, in responding, further detailed the objects which the promoters of the Medical Graduates' College and Polyclinic had in view. He drew attention to the opportunities which were afforded to medical men to increase their knowledge of the special branches of medical science. Mr. Hutchinson proposed the toast of "The Hospitals and Kindred Institutions," and expressed the desire that the college might work in coöperation with the large hospitals and the principal medical societies. The toast was suitably responded to by the Hon. Sydney Holland who said that he sincerely trusted that the committee of the Medical Graduates' College would not attempt to start another hospital, but would seek to associate themselves with some existing hospital. The toast of "Our Guests" was proposed by Sir Joseph Fayrer and responded to by Mr. Brudenell Carter. The health of the chairman was proposed by Dr. Stephen Mackenzie.

THE "GOUTTE DE LAIT" SOCIETY.

UNDER the above title a society has for some time been at work in France, and Dr. Alfred Hill, the medical officer of health of Birmingham, has made certain inquiries with regard to it. The object of the society is the very laudable one of the reduction of infantile mortality. The method of procedure is by the substitution of a suitable for an unsuitable diet: (1) by encouraging mothers to nurse their offspring; (2) by furnishing a specially prepared milk to meet those cases in which the first of these propositions cannot be carried out; and (3) by arranging for the infant to have the exact quantity of prepared milk necessary. The efforts of the society are directed mainly towards the poorest class, and to them the daily quantum of milk is furnished for one penny. The artisan class is charged 3*d*. and the upper class 6½*d*. The infants thus provided for are weighed frequently with a view of judging as to an increase or decrease of the milk allowance. All milk supplied is sterilised. Dr. Hill reports to the Birmingham Corporation that this system is being attended with great success, there being a very marked decrease in the infantile mortality at places adopting these methods of milk-supply. Certainly the experiment is worthy both of study and encouragement; a diminishing supply of child life calls for vigorous steps to prevent an excessive infantile mortality.

ALARM OF PLAGUE IN SMYRNA.

IN THE LANCET of May 19th (p. 1456) it was mentioned that a case of suspected plague had been discovered in Smyrna and isolated outside the city on May 8th. On May 9th Dr. Cozzonis of Smyrna telegraphed to Constantinople a further description of the patient's symptoms which, although serious, were not precisely those of plague. The bubo in his right groin was still painful when touched, but his medical attendant, Dr. Amado, said that he had suffered from a similar bubo some years ago. His abode, which was a damp and unwholesome place nearly three feet under ground, was disinfected and closed. On May 16th Dr. Cozzonis telegraphed to Constantinople that Dr. Nouri Bey had examined pulp from the bubo microscopically and by inoculation of rabbits. The results were negative, but characteristic lesions were produced in guinea-pigs by inoculation with cultures of three days' growth; the animals, however, did not die. The patient was improving and the conclusion was that very few germs were present. No dead rats had been found. On May 28th Dr. Mizzi, *médecin sanitaire* at Smyrna, telegraphed to Constantinople that a Jewish carpenter, 23 years of age, a patient under the care of Dr. Corris, was suffering from pyrexia and enlargement of several glands in the right groin without any concomitant lesion to account for them. Both the patient and his friends declared that they had never been in the neighbourhood of the case already isolated; the abodes of the men were about 400 yards apart. The second case was immediately isolated outside the city and both patients were inoculated with anti-plague serum. Plague still continues at Jeddah and is spreading on the Turco-Persian frontier.

THE HEALTH OF GIBRALTAR.

THE population of this little peninsula varies but slightly and the census figures of 19,100 are still, the medical officer of health reports, applicable. The birth-rate for 1899 was 31·34 and the death-rate 22·03 per 1000. There were nine cases of small-pox with one death during the year, the source of infection having apparently been the Spanish Lines where the disease was prevalent. Primary vaccination is well carried out in Gibraltar, but revaccination is rarely practised. In the matter of milk supervision an example is set to this country by the registration of the street-vendors, stringent control being essential owing to the insanitary condition of the Spanish cowsheds. Major H. P. Elkington, R.A.M.C., the medical officer of health, suggests the establishment of a farm within the British lines, or, failing this, the milk should be sterilised. As regards water-supply it is interesting to note that arrangements have been made for an additional supply of rain-water, four large reservoirs having been constructed in the limestone rock in such fashion that neither bombardment nor fluctuations of temperature will affect the water stored therein. Before use the water will be filtered through "polarite" and aerated by falling as a spray through a distance of some 50 feet. Service pipes are apparently not in use in Gibraltar and Major Elkington strongly advises their establishment. He has, it would seem, no fear as to the action of the water on lead and he strongly condemns the present system of hawking water about the streets.

THE DUTIES OF AN ASYLUM SUPERINTENDENT.

A RECENT number of the *Portadown News* (May 19th) contains an account of the monthly meeting of the Board of Management of the Lunatic Asylum at Portadown, at which various opinions were expressed by the members concerning what they conceived should be the duties of a medical superintendent. Among such duties—in addition to the professional duties—expected of the medical superintendent appeared the following: keeping the subsidiary financial account of the institution, the care and supervision of china and crockery, and the planting of potatoes. The question of acquiring additional land was negatived as the committee were unanimously of opinion—considering that Mr. G. R. Lawless (the resident medical superintendent) did not know when potatoes should be planted—that there was no need of additional land. Among other things which fell within the medical superintendent's province was the selling of old clothes belonging to the patients as ordered by the board, though he (the medical superintendent) was of opinion that such clothes should be destroyed. On the motion of Mr. Best, seconded by Mr. Armstrong, "the board further instructed the medical superintendent to have mortar made on the grounds," and to keep a supply of the same for the needs of the institution. A member of the committee inquired if they could feed more pigs than they had at present and Mr. Lawless replied that they had not accommodation for more. The *Portadown News* concludes its report as follows concerning the committee and their doings: "After the meeting was over several of the governors visited the piggeries, and on finding that a number of them (the pigs)

were over two hundredweight and that in the ordinary course it would be two months before they could be disposed of by tender, it is said that some unprintable expressions were used regarding the management of the institution in general." It appears clear that the medical and professional duties required to be performed by the medical superintendent as the responsible physician in charge of the patients and of the administration of the asylum could not be performed were he to have to do the other work required by the committee. Evidently some of the committee think that the superintendent should be made a beast of burden and a jack-of-all-trades—a state of things which is not conducive to the best interests of the public asylum service if a medical officer in charge of patients is required to do the work of a steward, an accountant-clerk, a farm-bailiff, a housekeeper, and a manager of the piggeries.

A CYCLING DANGER.

A CYCLING accident which occurred near Leeds on May 26th is no less instructive than it is regrettable. The rider, while descending a steep hill with his feet on the rests, came at great speed against a parapet at the foot of the descent, was thrown over with his machine, and was buried in the mud of the canal which flowed beneath. When extricated he was dead. Such an occurrence is not singular. It has happened before under almost identical conditions. With some variation in details it has probably been less unusual than is commonly understood. For its prevention it is vain to search among mechanical contrivances. Not even the free wheel allows the cyclist such a measure of control as to ensure his safety in the circumstances which we have recorded. There is only one possible remedy, that is resolutely to refrain from riding down hill, and especially from "coasting," unless the rider feels assured of his control over his machine and understands the road he is travelling. The slope may end with a sharp curve or with more than one such in succession, or a country cart may be mounting the hill unseen and very possibly, too, on the wrong side. In either case there is danger, no matter how expert the cyclist. Yet not a few ride down hills which are notoriously dangerous and are so marked in the road maps. Another cause of accident is to be found in the habit of riding with the head down, the handle-bars being placed low. Of course, the rider can avoid this if he pleases and he ought certainly to do so when on a declivity. Even on a flat road there is strictly no more reason for the amateur to ride stooping than there is for an ordinary rider to sit like a racing jockey. To ride a bicycle so down a hill-slope is only to court misfortune.

LORD LISTER has consented to open the new clinical laboratories at the Westminster Hospital on Tuesday next, June 12th. Amongst those who have accepted the invitation of the president, treasurers, and committee to be present on the occasion are Lord Kelvin, the Dean of Westminster, Sir Michael Foster, the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, Sir John Burdon Sanderson, and Sir Joseph Fayrer.

THE St. Petersburg Military Medical Academy has received a considerable grant from the Minister of Finance in order to establish a clinic for persons suffering from the effects of alcoholism.

WE regret to announce the death at an early age of Dr. G. E. Williamson, F.R.C.S. Eng., surgeon to the eye department, Royal Infirmary, Newcastle-on-Tyne.

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.

JUDGING by the satisfactory attendance of visitors, comprising medical men, pharmacists, hospital nurses, and others, "the fourth annual exposition of professional exhibits," which was held this week at the Queen's Hall, Langham-place, attained a success not less in degree than that which has marked former occasions. As we have pointed out before, this annual exhibition affords an excellent opportunity to practitioners in London of inspecting new preparations, appliances, and other objects of medical interest. Further, the exhibition being necessarily held on a small scale a good deal may be seen without experiencing that sense of fatigue which is commonly felt after a tour along row upon row of stalls. The exhibition at the Queen's Hall on the present occasion was tastefully arranged and very compact. One advantage which the hall offers for the purpose is that it is carpeted, so that the irritating noise of shuffling boots on plain wooden flooring is avoided, which makes conversation comfortable and enables the exchange of opinion between the exhibitors and the visitors to be carried on without interruption. The exhibition was opened on Tuesday, June 5th, by the president of the Organising Committee, Mr. Fred Weiss. In the course of a short and appropriate speech Mr. Weiss stated that every year showed an increase in the attendance of visitors, which fact was evidence of the increasing popularity of the exhibition. There was an increase last year of 2000 visitors over the previous year, the attendances being respectively 4000 and 6000. At the time when Mr. Weiss declared the exhibition open, which was shortly after 2 P.M., there were still a few stalls unfinished, but on the whole the organisers may be congratulated on having the exhibition practically ready for visitors at the time announced.

There was an abundant display of drugs, comprising the most recent introductions both in regard to special forms of administration and novelty of composition. The stall of Messrs. Cooper and Co. of 80, Gloucester-road, South Kensington, London, S.W., presented an excellently arranged and attractive display of drugs, special foods, and mineral waters. This firm prepares mineral water aerated both with oxygen and carbonic acid gas and very special precautions are taken to ensure the purity of the distilled water used. The water may be obtained plain, when it is known as "Globenaris," or it may be procured with definite amounts of lithia, piperazine, soda, and other soluble medicaments. The exhibit included also the flexible, tasteless, and readily soluble wafer capsules known as "cachoids" and other special preparations. A great number of interesting preparations were shown at the exhibit of Mr. W. Martindale of 10, New Cavendish-street, London, W. In addition to well-known drugs in various attractive forms there were amongst the specimens bacteriological culture media, stains and reagents, and other apparatus. The portable urine test case is very useful, as we have shown, for the requirements of the busy medical man, for it enables him to conduct an analysis sufficiently accurate for clinical purposes at the bedside. Amongst the interesting specimens of drugs shown were cacodylic acid which has recently been employed in the treatment of phthisis, and the sodium salt which is an excellent means of administering arsenic per rectum. Close by was the well-stocked stall of Messrs. Parke, Davis, and Co., of 111, Queen Victoria-street, London, E.C. A greater variety of drugs and related preparations, as well as various methods for their administration, could hardly have been displayed. The standard fluid extracts of this firm are well worth attention, as affording a fluid preparation containing definite active principles in known proportion. The drugs are carefully assayed before the extract is prepared, both chemically and when necessary physiologically, so that the therapeutic activity of a given measure of the extract may be relied upon. The exhibit included serums and toxins, euthymol preparations, antiseptics, mercurol, a nucleide of mercury which we dealt with recently in our analytical columns, and that interesting and powerful enzyme taka-diastase. The chocolate-coated tablets of this firm are also worthy of commendation. A very interesting series of pure chemicals,

alkaloids, and other preparations was exhibited by Mr. E. Merck of Darmstadt and 16, Jewry-street, London, E.C. This firm has a well-known reputation for the purity of fine drugs, and also in being enterprising in the manufacture of new pharmaceutical preparations which are suggested from time to time in medical practice. The exhibit included some organic iodine and bromine preparations and hæmoglobin. The preparations shown were excellent specimens of the art of obtaining pure crystallisable as well as non-crystallisable products in the laboratory. Some new interesting pharmaceutical products were shown by Messrs. Burgoyne, Burbidges, and Co., of 12 and 16, Coleman-street, London, E.C., who are the sole agents for the United Kingdom for Von Heyden's pharmaceutical products. Creosotal and duotal, which are respectively the carbonates of creosote and guaiacol, are examples. Besides these there were the interesting preparations known as "Collargolum," a form of metallic silver, but non-irritating and non-poisonous although a powerful antiseptic, and "Hyrgolum," which is described as "water soluble metallic hydrargyrum." As we have recently shown, this latter substance yields a clear but dichroic solution in water, and this novel substance in the form of an ointment is said to be more effective than ordinary mercury. The special preparation known as Wampole's perfected and tasteless preparation of the extract of cod-liver oil was submitted for inspection by the representative in this country, Dr. E. A. Martin, 4, Duke-street, Adelphi, London, W.C. As we have before pointed out it contains certain alkaloidal and other principles found in the liver of the cod, but the oil is carefully eliminated In addition to these it contains the hypophosphites, fluid extract of wild cherry bark, and extract of malt which contribute in no small degree to the undoubted tonic qualities of the preparation. Clinical experience is quoted in proof of the statements in regard to its administration in debility. Synthetics were, as might be expected, largely exhibited by the Bayer Co., Limited, of 19, St. Dunstan's-hill, London, E.C., and Elberfeld. Amongst comparatively recent introductions should be mentioned aspirin, a substitute for the salicylates which is said to avoid their unpleasant effects; heroin, a substitute for codeine; and protargol or proteinate of silver which has been used in the treatment of gonorrhœa. A stainless iodine ointment known as "Kelpion" is being introduced by the Kelpion Company, Norgrove Buildings, 59A, Bishopsgate-street Within, London, E.C. Kelpion is stated to be quite non-irritating, and statements are made in favour of its use in rheumatism and syphilis. Messrs. Arthur and Co., of 69, Berners-street, London, W., brought forward their well-prepared gold compounds; the one known as "Bromaurum," which is a brom-arsenate of gold, apparently acts in preventing the formation of urohæmatoporphyrin and in controlling the morbid process characteristic of muscular and chronic rheumatism. Samples of uric acid illustrating the control over the disease (by different degrees of pigmentation) were shown. Similarly samples of pigmented uric acid were shown illustrating the influence of an excess of alcohol in promoting the secretion of hæmatoporphyrin in antagonism to bromaurum. The exhibit included other well-known preparations which are specialities of this firm, as for example, sanochinol, described as a new atoxic derivative of quinine and a remedy for tropical fevers; tannopumilio, a remedy for irritation of the skin and bromidrosis, a compound of digallic acid with the principle of the essential oil of the pumilio pine. Messrs. Wyley's, Limited, of Coventry devoted the space on their stall chiefly to some excellent administrative forms of drugs, such as cachets, capsules, gelatin-coated pills, and "tropels" or compressed lozenges. Some elegant pharmaceutical preparations artistically relieved this display. Messrs. Oppenheimer, Son & Co, Limited, of 179, Queen Victoria-street, London, E.C., made a feature of palatinoids and bi-palatinoids in their well-arranged exhibit. There are many applications of this ingenious form of vehicle for drugs which deserve attention. In the first place the palatinoid administers the drug in the powdered condition, while preserving the contents against deterioration from atmospheric influences. An important application, too, of the palatinoid appears in the case of animal substances. Amongst the other specialities shown by this firm were palatinoids of liquids and tinctures and bi-palatinoids of Easton's syrup. Messrs. F. Newbery and Sons, of 27 and 28, Charterhouse-square, London, E.C., exhibited largely on behalf of Messrs. W. R. Warner and Co., of Philadelphia and New York, although the exhibit included a very comprehensive series of their own granular effervescent salts. Perhaps the most interesting and important subjects of exhibits by Messrs. J. F. Macfarlan and Co., of 93 and 109, Abbey-hill, Edinburgh, and of 9 and 11, Moor-lane, London, E.C., were the double cyanides of mercury and zinc used for the well-known dressing introduced by Lord Lister. The exhibit included the specially purified chloroform for which this firm holds a deserved reputation. In addition were the opium derivatives, morphine benzoyl, morphine diacetyl, and morphine ethyl hydrochlorides, which are said to be milder and less toxic than morphine and codeine and more certain in their action. Vitæ Ore affords a simple and ready means of producing a chalybeate water with tonic properties. As we have shown, it consists of oxidised pyrites and its properties were explained to the visitors by representatives of the Vitæ Ore Co., Limited, of 39, Temple-chambers, London, E.C. Amiral Soap may be mentioned in this paragraph, since the soap is but a vehicle for applying certain bile principles which are said to reduce corpulency by simple application to the skin. It is said to reduce the excessive fat of the body wherever applied, but on this point some evidence would seem to be required upon medical authority. The exhibitors were the Amiral Soap Co., Limited, 3, Throgmorton-avenue, London, E.C.

We shall continue our account next week by dealing with the special foods and other articles of interest which were on exhibition.

(To be continued.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

ON Thursday, July 5th, a meeting of the Fellows will be held for the election of four members of Council. In consequence of the additional year of office of Sir William Mac Cormac, Bart., K.C.V.O., coming to an end during his presidency he will remain a member of the Council for another year.

The following list of the 24 members of the Council gives the date at which each member retires:—

Retire in 1907.—Mr. T. R. Jessop, Leeds General Infirmary (first elected 1891); and Mr. H. W. Page, St. Mary's Hospital.

Retire in 1906.—Mr. F. Richardson Cross, Bristol Royal Infirmary; Mr. Henry Morris, Middlesex Hospital; and Mr. John Langton, St. Bartholomew's Hospital (first elected 1890).

Retire in 1905.—Mr. H. G. Howse, Senior Vice-President, Guy's Hospital (first elected 1889); Mr. Edmund Owen, St. Mary's Hospital; and Mr. Rickman J. Godlee, University College Hospital.

Retire in 1904.—Mr. Thomas Bryant, Guy's Hospital (first elected 1880); and Mr. T. Pickering Pick, St. George's Hospital (first elected 1888).

Retire in 1903.—Mr. A. Willett, St. Bartholomew's Hospital (first elected 1887); Mr. H. T. Butlin, St. Bartholomew's Hospital; and Mr. F. Treves, London Hospital.

Retire in 1902.—Mr. Reginald Harrison (first elected 1886); Mr. Howard Marsh, St. Bartholomew's Hospital (first elected 1892); and Mr. J. Hardie, Royal Infirmary, Manchester.

Retire in 1901.—Sir William Mac Cormac, President, St. Thomas's Hospital (first elected 1883); Mr. N C. Macnamara, Westminster Hospital; Mr. A. W. Mayo Robson, Leeds General Infirmary; and Mr. W. Watson Cheyne, King's College Hospital.

Retire in 1900.—Sir Thomas Smith, St. Bartholomew's Hospital; Mr. J. Tweedy, Junior Vice-President, University College Hospital; and Mr. Alfred Cooper.

A fourth vacancy is occasioned by the death of Mr. Davies-Colley, whose term of office would have come to an end in 1904.

Sir Thomas Smith does not intend, we understand, to apply for re-election.

For the four vacancies two of the retiring members of the Council—viz., Mr. Tweedy and Mr. Cooper—are applying

for re-election. A former member of the Council, Dr. J. Ward Cousins of Portsmouth, is again coming forward, and ten other Fellows are offering themselves. These are Mr. C. H. Golding-Bird and Mr. R. Clement Lucas of Guy's Hospital; Mr. H. H. Clutton, of St. Thomas's Hospital; Mr. W. H. Bennett, of St. George's Hospital; Mr. John H. Morgan and Mr. J. A. Bloxam, of Charing-cross Hospital; Mr. A. Pearce Gould and Mr. J. Bland-Sutton, of Middlesex Hospital; Mr. W. J. Walsham, of St. Bartholomew's Hospital; and Mr. Jordan Lloyd, of Birmingham.

It is quite possible that all these thirteen candidates may not go to the poll. Nomination forms must reach the secretary by Monday, June 11th. At present St. Bartholomew's Hospital has five representatives; Guy's Hospital, University College Hospital, and St. Mary's Hospital have respectively two representatives; and the following hospitals have one representative apiece: St. George's, King's College, London, Middlesex, St. Thomas's, and Westminster. Two members of the Council are connected with special London hospitals and four are attached to provincial hospitals; Leeds General Infirmary has two representatives and Bristol Royal Infirmary and Manchester Royal Infirmary have each one.

THE PREVENTION OF TUBERCULOSIS.

THE interest in the prevention of tuberculosis, we are glad to see, is by no means abating, and the various local bodies throughout the country continue to further the erection of sanatoria and other means of fighting the disease which is responsible for so many deaths yearly.

PLYMOUTH.

The Borough Council of Plymouth at their meeting held during the second week in May received a report from the Sanitary Committee stating that a deputation from the Devon and West Cornwall Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis had waited upon them and had submitted a scheme for the voluntary notification of phthisis. The Sanitary Committee recommended that the scheme should be adopted and that notifying medical practitioners should be allowed a fee of 2*s*. 6*d*. for each private patient, and a fee of 1*s*. for each parochial or dispensary patient, notified. The recommendation was unanimously adopted.

DUNDEE.

The city of Dundee is about to erect a sanatorium for the treatment of tuberculous patients, the expenses of which are to be mainly defrayed out of the very generous gift of £10,000 contributed by ex-Provost Moncur. The plans were approved by the Works Committee on May 14th. The site is on the Airlie estate and has been given by Lord Airlie. The whole establishment is to cover an area of between 20 and 30 acres and the building will consist of three blocks. The residential block will hold 34 patients and will have a frontage of 200 feet, and there is accommodation for the matron, nurses, and resident medical officer, as well as for the patients. The second block is devoted to a dining-room, kitchens, and offices, while the third contains a laundry and a lighting plant.

YORKSHIRE.

The annual meeting of the Yorkshire Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was held on May 14th in the Museum of York, Mr. Alderman E. Gray being in the chair.—Dr. W. A. Evelyn read the report which showed that the committee appointed to inquire into and to decide upon a site for the erection of a sanatorium had not yet been able to come to a conclusion. During the year 1899 there were 48 deaths of children under the age of five years from tuberculous diseases. This gave a rate of about 20 per 1000 births. There is great scope for the York branch to work for the promotion of a pure milk-supply.

LIVERPOOL.

A public meeting was held on May 18th in the Town Hall, Liverpool, its inception being due to an earnest request from the medical profession in Liverpool that a Liverpool Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis should be inaugurated. The Lord Mayor presided, and there were also present Lord Derby, Sir William Mitchell Banks, the Rev. J. Bell Cox, a large number of local medical men (including Professor Rubert Boyce), while Mr. Malcolm Morris came from London and Dr. Arthur Ransome from Bournemouth. An account of this meeting has been already given by our Liverpool correspondent.[1]

ARMY MEDICAL REPORT FOR 1898.[2]

SECOND NOTICE.[3]

IN our previous notice we took a preliminary canter, as it were, over the ground which is occupied by the last published volume of the annual series of these reports, and gave a brief and cursory outline of its contents accompanied by a summary statement of the general health conditions of the troops at home and abroad during 1898. Our purpose now is to select a few points of interest which lend themselves to consideration and comment rather than to touch upon the classified statistical results at the different stations or to compare these with one another. Those of our readers who are more particularly interested in such matters will naturally refer to the report itself for information. As everyone knows public interest is absorbed at the present moment, almost to the exclusion of everything else, in the events which are taking place in South Africa. A glance at the daily journals is unfortunately sufficient to show the important rôle which disease, and notably enteric fever, occupies in the history of the present war. This fever is a veritable scourge of armies in the field and this has been even more the case with the expeditionary armies of other military powers than with ourselves. We find abundant evidence of the prevalence of enteric fever in South Africa in the report under review—at Ladysmith, Pietermaritzburg, Wynberg, King William's Town, and Simonstown, for example—long before the arrival of the British expeditionary force had taken place in that country, and we are therefore not required to have recourse to the theory of any fresh introduction of the disease there by the newly arrived troops. As the subject is one of vast importance in relation to the diseases incidental to war service and camps we need make no apologies for dealing with it more especially. As we have said on previous occasions it is a generally recognised fact, be the explanation what it may, that there is an increased liability to contract enteric fever at certain periods of life; in other words, that there exists an enteric fever age-period which includes the time during which soldiers are serving with the colours in all short-service armies. But a still more powerful predisposing factor is recent arrival in a tropical or subtropical climate, especially during the hot season. We all know what the heat has been in South Africa, that most of the troops were young soldiers, and that all may be said to have newly arrived there. As far as India is concerned this susceptibility or vulnerability of the European constitution to enteric fever of fresh arrivals is at its maximum during the first year, markedly declines during the second and third years, and is, practically speaking, nearly exhausted between the third and fourth years of Indian service. It is not, of course, pretended that these are the only disease-factors, for if the real cause of enteric fever be the bacillus of Eberth and Gaffky then it follows that the presence of that specific germ or micro-organism is indispensably necessary to its production; but this bacillus must in that case be much more widely distributed in nature than our present knowledge would lead us to suppose in order to account for all the enteric fever that occurs, or, to put it another way, the number and extent of the infected areas on the surface of the globe must be greater than has been hitherto thought to be the case. Dr. Horton-Smith's recent Goulstonian lectures at the Royal College of Physicians of London on "The Typhoid Bacillus and Typhoid Fever" have opened out a wide field for further investigation in various directions, but especially in this respect that it has been found to be not uncommon for the

[1] See THE LANCET, May 26th, p. 1549.

[2] Army Medical Department. Report for the Year 1898, with Appendix. Vol. xl. London: Printed for Her Majesty's Stationery Office by Harrison and Sons, St. Martin's-lane, Printers to Her Majesty. 1900. Price 2*s*. 6*d*.

[3] The first notice was published in THE LANCET of May 12th, 1900, p. 1384.

bacillus to remain dormant for long periods of time in the bodies of those who have been attacked and have seemingly quite recovered and meanwhile remained in perfect health. Assuming that to be the case such individuals may prove so many sources of hitherto unrecognised infection. Touching the liability of the young soldier to contract enteric fever in the first year of his Indian service this is very strikingly brought out in the chart illustrative of the relation of service in India to cases of this fever which appears at page 179 of the Army Medical Report for 1898. The admission ratio of 91·5 per 1000 in that year is out of all proportion to those that follow in subsequent years, the next highest being 38·0 for men of the second year of service, while it is only 1·0 per 1000 for those of 10 years' Indian service and over.

The principal medical officer (Surgeon-General W. Taylor, C.B., A.M.S.) writes as follows concerning enteric fever amongst the troops in India:—

> The liability of troops on service to enteric fever, even when encamped on what appears to be virgin soil, is a fact in regard to which almost all observers are unanimous, and a considerable part of the increase in both the admission and mortality rates for 1898 can be accounted for by field service. The chief instances of increase from this source are the outbreaks in the Khyber and Malakand Forces, admissions from troops returned and passing through from field service at Rawal Pindi, and importation by regiments arriving from the front at Ahmednagar, Fyzabad, and Cawnpore. A second large source of increase was the Quetta epidemic. A small part of the increased admission rate may be due to improved means of diagnosis. Thus, at Quetta Widal's test was employed in 82 cases and was much relied on for the differentiation of typical cases. It was also used at Rawal Pindi and Ahmednagar.

Whilst on the subject of enteric fever in relation to troops on field service there is also another point to be considered. We remember that an army medical officer some years ago called attention to the fact that the period of incubation in the cases of soldiers returning from a campaign where enteric fever was epidemic or prevalent was often of a very prolonged kind in those attacked, and he cited numerous examples that had fallen within his experience. Turning to page 264 of the Army Medical Report dealing with Egypt and Cyprus we find the following statements which seem to be strongly corroborative of this and worthy of further attention. The table shows the period elapsing between the development of attacks of enteric fever and the data of the return of the individuals from "Up Nile" in all those cases which occurred amongst troops previously serving with the Khartoum Expeditionary Force.

Number of Cases of Enteric Fever occurring—

Stations.	Within first week after return.	Within second week after return.	Within third week after return.	Within fourth week after return.	Within fifth week after return.	Within sixth week after return.	Within seventh week after return.	Within eighth week after return.
Alexandria	14	19	49	31	12	3	1	—
Cairo	31	39	31	29	6	15	10	1
Cyprus	—	—	—	—	—	—	—	1
Total	45	58	80	60	18	18	11	2

Return of Cases of Enteric Fever occurring in Soldiers more than eight weeks after their Return from the Khartoum Expedition, 1898.

Date o return from the Soudan.	Date of admission to hospital.	No. of cases.
Sept. 15th, 1898	Nov. 23rd, 1898	7

,, ,, ,, ...	,, 27th, ,, ...	

It might, of course, be said that such cases caught it from one another after return from field service or that they were really suffering from the disease during longer and more variable periods than was supposed.

So far as our present experience extends—for we must await the official publication of the statistical results obtained during the present war before arriving at any final conclusion—it does not seem that the practice of inoculation as a safeguard against typhoid fever has been attended with that amount of success which had been hoped.

THE WAR IN SOUTH AFRICA.

IT is easy to sum up the war news of the week in a sentence. Pretoria is in our possession and the Union Jack now flies where the flag of the Transvaal Republic has flown for nearly 20 years. The entry of the British force into the capital of the Transvaal under Lord Roberts is an epoch-making event in history and the importance of the success which has been achieved has probably not even yet been thoroughly appreciated; but everybody recognises that with the fall of Pretoria the back of the Boer rebellion has been broken and that a long and painful chapter in the annals of our South African Dominion has been closed.

Although the war is not over we may confidently hope that a new and better era has been opened for all concerned with South Africa, not excluding the Boers themselves, for when the political settlement and arrangements have been made the same political freedom and equality of opportunity will be extended to all alike. But as we have said the war is not yet over. There remains a large body of discontented Boers scattered over the country who may still be expected to retain and exhibit signs of vitality and separate and independent action for some time to come, for their troops have usually succeeded in their encounters with us in effecting their retreat and in carrying off their guns. Still the Boer forces have no longer any organic cohesion. They have hitherto shown no strategical ability and are not likely to do so now, and their power to harass our troops and prolong the campaign by a guerilla system of warfare must inevitably become weaker and weaker until it finally ceases altogether. The sudden collapse of the burgher forces has demonstrated the hopelessness of resistance by unorganised armed forces, however brave, when opposed to a trained and disciplined army intelligently conducted.

There is still a large amount of enteric fever among the British troops in South Africa and the sufferings undergone by these unfortunate patients must be considerable under all the circumstances of this war, for they have usually to be transported for long distances to stationary hospitals in the rear where many of them arrive in a very pitiable condition. Although such large quantities of clothing and medical comforts have been sent out from this country by the Government and the numerous sources of charitable supply we do not think, from what we hear, that there is any reason for the public to relax their efforts, for the sick coming down from the front are in need of ample supplies of clean and warm clothing of all kinds. It is, after all, not so much the wounded who claim our help and sympathy in war as the sick—those suffering from enteric fever, dysentery, and acute respiratory affections. Their hardships, sufferings, and discomforts make up in the aggregate a terrible total, because, as we all can recognise, the many unavoidable conditions of war and field service are so unfavourable and inimical to cases of this nature.

The Imperial Yeomanry Base and Field Hospitals are increasing their accommodation in consequence of the large number of cases of enteric fever and kindred diseases. Further equipment is being sent out as rapidly as possible, and 10 additional nurses have left within the past few days. The field hospital and the bearer company have left Bloemfontein for the front.

Major-General the Hon. Herbert Heaton, the hon. secretary of the Portland Hospital, has received a letter from Surgeon-Major C. R. Kilkelly, R.A.M.C., commandant of the hospital, showing that from Jan. 8th to May 11th 92 officers and 613 non-commissioned officers and men were admitted into the hospital. When the letter was despatched 25 officers and 95 men still remained under treatment. Of the others 97 officers and men had been discharged for duty,

five discharged for garrison duty, and 98 sent to England. Four officers and 254 men were convalescent, 114 officers and men had been transferred to other hospitals, and only one officer and nine men had died. We are extremely glad to notice that the case of the Indian and native stretcher bearers is not likely to be lost sight of, for these men have rendered very valuable services in the present war which thoroughly deserve to be rewarded.

SICK AND WOUNDED OFFICERS' SURGICAL AND MEDICAL AID COMMITTEE.

This committee, which includes many members of the profession in London and elsewhere, met on Wednesday last, June 6th, at Hampden House under the Presidency of the Duke of Abercorn to receive the report of the work accomplished to the present date. The management of the funds subscribed, the recommendation of invalided officers to the professional members of the committee, and the allocation of convalescents to the various private houses and hotels which have been kindly offered for their use is deputed to a confidential executive committee consisting of the following members: the Duke of Abercorn, the Hon. Arthur Brodrick (who acts as honorary secretary), Lieutenant-Colonel H. Charlesworth, R.A.M.C., and Colonel Stacpole, D.A.A.G. (who superintend the disembarkation of invalided officers at Southampton), Mr. Lyttelton Gell, Surgeon-General Hamilton, A.M.S., Dr. Donald Hood, Mr. F. A. Johnston, and Mr. J. H. Morgan.

The President reported that since the last meeting the following gentlemen had been added to the General Committee: Sir Felix Semon, Sir William MacCormac, Mr. Frederick Treves, Mr. Howard Marsh, Mr. Mackenzie Davidson, and Mr. Warrington Haward. Lieutenant-Colonel Knocker, A.A.G., Devonport; Lieutenant-Colonel Bourke, R.A.M.C., Woolwich; and Lieutenant-Colonel McLeod, D.A.A.G., Chatham, were elected members at the meeting.

In addition to the invaluable assistance rendered by physicians and surgeons on the committee over 200 offers of hospitality in private houses and from hotels (either gratuitously or on reduced terms) have been received either directly or have been transmitted to the committee by the War Office.

Many officers have already availed themselves of these invitations, though the chief demand upon them is likely to arise at a later date. The coöperation of the Countess of Dudley in arrangements for the wives or other relatives accompanying invalided officers has been very gratefully appreciated. 60 officers have already been assisted by the Executive Committee, while others either through their private circumstances, or through the improvement in their health during the voyage home, have not required the committee's assistance. 160 officers are at the present moment on their way to England, of whom a large proportion are likely to accept the committee's help; and the President called attention to the resolution passed at a previous meeting that surgeons or physicians who were consulted by such officers should receive a letter signed by a member of the Executive Committee. The cases which have so far received surgical or medical assistance from members of the committee fall under the following heads. 34 surgical cases have been dealt with and five new cases are coming forward at the present moment. 22 have had advice and treatment, several of whom have been sent to the country or abroad. Two have returned to South Africa for service. Ten have required operations in surgical homes, two for wounds of the knee involving artery or nerves or both, one for arterio-venous aneurysm of the femoral, one for severe fracture of the femur, two for loose cartilages in the knee-joint, one for appendicitis, and one patient has had fragments of lead removed from the thigh and scrotum, while three cases of amputation of the leg with stumps not healed, two cases of perforating wound of the chest and lung, and one case of gunshot fracture of the humerus with injury of nerve have been treated. One patient recovered after receiving five wounds one of which penetrated the abdomen. One patient was hit by four bullets, one of which fractured the left femur high up. He has been sent abroad. In the majority of cases of severe wounds the results of nervous shock have been marked and have in several instances lasted so long as to require rest and change before operation could be undertaken. Cases of injury to nerves have improved greatly under massage and change of air.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 33 of the largest English towns 6932 births and 3951 deaths were registered during the week ending June 2nd. The annual rate of mortality in these towns, which had increased from 17·8 to 18·4 per 1000 in the three preceding weeks, declined again to 17·7 last week. In London the death-rate was 17·0 per 1000, while it averaged 18·2 in the 32 provincial towns. The lowest death-rates in these towns were 11·0 in Gateshead, 11·1 in Croydon, 12·6 in Brighton, and 13 5 in Derby; the highest rates were 22·1 in Blackburn, 22 2 in Swansea, 22·8 in Halifax, and 25·5 in Plymouth. The 3951 deaths in these towns included 423 which were referred to the principal zymotic diseases, against 431 and 443 in the two preceding weeks; of these 142 resulted from measles, 115 from whooping-cough, 77 from diphtheria, 34 from diarrhœa, 29 from scarlet fever, and 26 from "fever" (principally enteric). No fatal cases of any of these diseases occurred last week in Norwich or in Gateshead; in the other towns they caused the lowest death-rates in Croydon, Brighton, Birkenhead, and Halifax, and the highest rates in Wolverhampton, Lercester, Derby, Blackburn, and Sheffield. The greatest proportional mortality from measles occurred in Plymouth, Cardiff, Derby, Blackburn, and Sunderland; from scarlet fever in Burnley; from whooping-cough in Wolverhampton, Salford, Oldham, and Huddersfield; from "fever" in Swansea; and from diarrhœa in Blackburn. The 77 deaths from diphtheria included 29 in London, nine in Leicester, nine in Sheffield, five in Birmingham, and four in Liverpool. No fatal case of small-pox was registered last week in any of the 33 towns. There were seven small-pox patients under treatment on Saturday last, June 2nd, in the Metropolitan Asylums Hospitals, and four new cases were admitted during the week. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1759, against numbers increasing from 1647 to 1784 on the five preceding Saturdays; 194 new cases were admitted during the week, against 203, 221, and 216 in the three preceding weeks. Influenza was certified as the primary cause of 14 deaths in London. The deaths referred to diseases of the respiratory organs in London, which had declined from 417 to 269 in the four preceding weeks, further declined to 266 last week, and were 15 below the corrected average. The causes of 36, or 0·9 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Leicester, Salford, Leeds, Newcastle, and in 12 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Halifax, Hull, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·7, 19·5, and 19·6 per 1000 in the three preceding weeks, declined again to 18·6 during the week ending June 2nd, but exceeded by 0·9 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 12·6 in Leith and 14·9 in Aberdeen to 20·7 in Glasgow and 23·6 in Perth. The 575 deaths in these towns included 25 which were referred to whooping-cough, 25 to diarrhœa, 16 to measles, four to diphtheria, one to small-pox, one to scarlet fever, and one to "fever." In all 73 deaths resulted from these principal zymotic diseases, against 85 and 76 in the two preceding weeks. These 73 deaths were equal to an annual rate of 2·4 per 1000, which was 0·5 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had risen from 22 to 36 in the three preceding weeks, declined again last week to 25, of which 21 occurred in Glasgow, two in Aberdeen, and two in Perth. The deaths from diarrhœa, which had been nine, 15, and 19 in the three preceding weeks, further rose to 25 last week, and included 13 in Glasgow, four in Dundee, three in Aberdeen, and two in Edinburgh. The fatal cases of measles, which had been 19 and 10 in the two preceding weeks, rose again last week to 16, of which 14 were registered in Glasgow. The deaths from diphtheria, which had been seven and five in the

two preceding weeks, further declined to four last week and included three in Glasgow, where the fatal case of small-pox was also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 84 and 94 in the two preceding weeks, further rose to 104 last week, but were slightly below the number in the corresponding period of last year. The causes of 41, or more than 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·0 and 25·2 per 1000 in the two preceding weeks, declined again to 21·9 during the week ending June 2nd. During the past four weeks the death-rate in the city has averaged 24·1 per 1000, the rate during the same period being 16·5 in London and 18·5 in Edinburgh. The 147 deaths belonging to Dublin registered during the week under notice were 22 less than the number in the preceding week, and included three which were referred to the principal zymotic diseases, against nine and five in the two preceding weeks; of these, one resulted from scarlet fever, one from "fever," one from diarrhœa, and not one either from small-pox, measles, diphtheria, or whooping-cough. These three deaths were equal to an annual rate of 0·4 per 1000, the zymotic death-rate during the same period being 2·0 in London and 0·5 in Edinburgh. The fatal case of scarlet fever was the only one registered during the last 10 weeks. The deaths from "fever," which had been three and two in the two preceding weeks, further declined to one last week. The mortality from diarrhœa showed a decline from that recorded in recent weeks. The 147 deaths in Dublin last week included 29 of infants under one year of age and 36 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a decline from the number in the preceding week. Five inquest cases and five deaths from violence were registered; and 62, or more than a third, of the deaths occurred in public institutions. The causes of seven, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: — Deputy Inspector of Hospitals and Fleets E. R. H. Pollard to the *Victoria and Albert*. Surgeon S. T. Reid to the *Pembroke*.

VOLUNTEER CORPS.

Rifle: 4th Volunteer Battalion the Queen's Own (Royal West Kent Regiment): The undermentioned gentlemen to be Surgeon-Lieutenants: William Watson, Arthur Tresco Franklyn Brown, and Herbert James Bryan. 1st Herefordshire: Surgeon-Lieutenant James Neil Macmullan resigns his commission and is appointed Second Lieutenant (supernumerary). 2nd Volunteer Battalion the East Lancashire Regiment: Surgeon-Captain A. A. Watson to be Surgeon-Major and to remain supernumerary. 1st Volunteer Battalion, the Lincolnshire Regiment: Surgeon-Lieutenant-Colonel H. Wright is borne as supernumerary whilst serving with the Royal Army Medical Corps in South Africa. 19th Middlesex: Surgeon-Lieutenant J. J. Clarke resigns his commission.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: Horace Stansfield Collier to be Surgeon-Lieutenant.

TRANSVAAL WAR NOTES.

The following officers were discharged from hospital to duty for the week which ended May 20th:—Royal Army Medical Corps: Major T. G. Lavie, Lieutenant C. S. Smith, Lieutenant M. H. G. Fell, Civil Surgeon Wynter, and Civil Surgeon Ashford. The following officers were discharged from hospital to duty for the week which ended May 18th:—Royal Army Medical Corps: Major A. Baird, Major R. Kirkpatrick, and Captain W. A. Ward.

A new infectious diseases block is being constructed in the grounds of the Military Hospital, Devonport, so that the whole of the existing blocks may be available for the wounded soldiers from South Africa.

Princess Christian will open a naval and millitary bazaar at Olympia on June 19th Mr. Goschen, M.P., will perform an opening ceremony on June 20th, and the Marchioness of Lansdowne on the third (the closing) day. Among the patrons of the bazaar, which is in aid of the Princess Christian's Home for Disabled Soldiers and Sailors, are Her Majesty the Queen and the Princess of Wales.

The Princess Christian Hospital, which has been presented to the Natal Government by Mr. Alfred Mosely, a Bristolian, was formally opened at Pinetown on May 18th by Colonel Morris, the military commandant. The Bishop of Natal (Dr. Baynes) was also present. The hospital, which is only for military purposes, has received patients since the commencement of April and contains 200 beds, all of which are now occupied. Mr. Mosely maintains the hospital at his own expense for four months, the estimated cost of this being £25,000.

The s s. *Cephalonia* arrived at Southampton from South Africa on the 3rd inst. She carried 418 invalids, who were admitted to the Royal Victoria Hospital.

TRANSVAAL WAR CASUALTIES.

LORD ROBERTS'S ADVANCE.

The following casualties are reported:—At Ladysmith, May 26th, Civil Surgeon Robert Irvine, from enteric fever; at Kheis, May 28th, Surgeon-Captain Dun, 5th Company Imperial Yeomanry, slightly wounded in leg; at Florida, May 29th, Lieutenant A. H. Benson, R.A.M.C., attached to Gordon Highlanders, slightly wounded.

ARMY MEDICAL SCHOOL, NETLEY.

Under orders from the Director-General A.M.S. a special examination was held in the Army Medical School, Netley, on May 29th, when the following surgeons-on-probation for the Royal Army Medical Corps were found duly qualified and were recommended for commissions as Lieutenants. They left Netley for Aldershot on Monday, June 4th: Mr. C. H. Carr, Mr. E. Bennett, Mr. F. P. Lauder, Mr. H. E. Weston, Mr. J. Tobin, Mr. A. C. Adderley, and Mr. G. E. Leary.

"Audi alteram partem."

INDURATED LYMPHATIC CORDS.

To the Editors of THE LANCET.

SIRS,—In his interesting lecture on Primary Syphilitic Chancres Mr. Jonathan Hutchinson, jun.,[1] draws attention to the occurrence of indurated lymphatic cords in from 40 to 50 per cent. of cases of primary syphilis, the importance of which "is not mentioned in any published description." The frequency of these, associated with chancres at the furrow or at the inner aspect of the prepuce, is noted, while their diagnostic importance is questioned. Apart from these valuable statistics and observations may I point out that the late Mr. Henry Lee[2] devoted especial attention to the subject? He described mainly two conditions:—1. The suppurating non-infecting syphilitic sore, from which the poison may be traced to the suppurating bubo, "in the clearest way" along the absorbent vessels and which may inoculate them, producing a fresh inoculable sore or occasionally a small abscess. 2. "A similar series of phenomena may be observed in the affections of the lymphatic vessels accompanying an indurated primary syphilitic sore ..... noticed by Hunter in which a lymphatic vessel leading from the chancre appears like a cord extending along the back of the penis. Sometimes these arise from thickening of the prepuce in cases of gonorrhœa. In such cases, however, the prepuce is generally excoriated. ..... The cord can be easily pinched up between the finger and thumb. ..... The lymphatics in such cases arise from an excoriated and inflamed internal prepuce. ..... We have here an account of the specific adhesive inflammation as it affects the lymphatic vessels, and although mixed up in Hunter's description with the suppurating form of the disease yet has he given the distinctive characters of each

[1] THE LANCET, June 2nd, 1900, p. 1575.

[2] Lectures on Syphilis (Lymphatic Absorption), Lecture IV., second edition, 1862. Hunterian and Lettsomian Lectures, Ibid., Lectures VII. and X., 1870.

with his usual clearness and precision." Essentially regarding induration as indifferently affecting either the lymphatic vessel or gland rather than apparently attaching importance to locality of lesion he noted that the induration of the vessel is often in inverse proportion to that of the primary sore or gland and he thought if such induration appeared shortly after infection and remained its "existence would be a sign of the patient being syphilitic" or, in less marked form, the subject of re-infection.

I am, Sirs, yours faithfully,

Grosvenor-street, W., June 5th. JOHN A. SHAW-MACKENZIE.

"THE RÔLE OF EDUCATION IN THE PREVENTION OF TUBERCULOSIS."

To the Editors of THE LANCET.

SIRS,—In my letter in THE LANCET of June 2nd, on the Rôle of Education in the Prevention of Tuberculosis, p. 1614, line 6, in the second column, "womankind" should be "mankind." Mr. Adler recommends among moral "duties" the inculcation of the laws of public and personal hygiene to children under the headings (*a*) duty to one's (physical, emotional, and intellectual) self—e.g., cleanliness, temperance, and chastity, &c.; (*b*) duty to mankind—e.g., justice, charity, &c.; and (*c*) duty to society—e.g., citizenship, parental and filial ties, &c. It may be equally claimed that such instruction in physical well-being is called for as an aid to morality. Practical illustrations of the effect of foul air might be shown with advantage to education and other authorities. This might bring the desired pressure to bear, as wished by the National Association.—I am, Sirs, yours faithfully,

F. BUSHNELL,

Honorary Secretary, Devon and Cornwall Association for the Prevention of Consumption.

Plymouth, June 5th, 1900.

THE LATE DR. G. F. CROOKE.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow us room to state what has been done regarding the Crooke Fund? The total amount subscribed is £219 14*s.* 6*d.* This we are handing over to Mr. J. T. J. Morrison—who was fellow-resident with Crooke at Guy's—and Mr. Arthur H. Foster, solicitor, of this city, who was his personal friend as well as legal adviser. They have consented to act as trustees, and we have not thought it wise to limit their powers except by the general instruction that the money was subscribed on the understanding that it would be used for the nurture and education of Crooke's only child—a little boy.

We are, Sirs, yours faithfully,

(Signed) A. FOXWELL, Treasurer of the Fund;
GILBERT BARLING, J. T. J. MORRISON, Secretaries.

Birmingham, June 4th, 1900.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—I have no intention of continuing this discussion. I beg to call attention to the fact that every point raised by Dr. Edmunds is fully dealt with in my report except the questions of albumin and sugar, both of which were absent.

I am, Sirs, yours faithfully,

Wigan, June 1st, 1900. GEO. MOWAT.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Plague and Cholera.—Official Indian Reports.—Increase of the Famine.

THE plague epidemic is subsiding throughout India. The returns for the week ending May 5th show the total plague deaths at 1771, compared with 2498 in the previous seven days. The plague mortality has dropped in Bombay city from 448 to 350 (these are the official figures and serve for comparison, but they are very wide of the mark); in Karachi from 284 to 187; in the Bombay Mofussil from 699 to 501; in Calcutta from 343 to 252; and in the Bengal Mofussil from 505 to 359. Notwithstanding the importation of one or two cases it is satisfactory to note that the cities of Madras and Rangoon have so far escaped. The present year has shown a remarkable diffusion of the epidemic. For the present a lull in the storm may be expected, but the forecast points to a further development after a period of rest. So many of the previous epidemics have lasted six, seven, and eight years that it is too much to expect that the present one will terminate this year. Cholera is now the chief pestilence and it caused no less than 811 deaths last week in Ahmedabad. It is raging also in some of the famine districts. The "normal" average for Calcutta is over 100 a week and for the whole of India half a million lives have often been lost in one year. The figures for plague look very small when the ravages of this disease are noted. Enteric fever is very prevalent in Rangoon. A committee of inquiry is about to be appointed. It will probably consist of the civil surgeon, the municipal engineer, three private medical practitioners, and possibly an engineer of the Public Works Department.

The official history of the progress of the plague in the Bombay Presidency has been published. It was compiled under orders of the Government by Captain Condon, I.S.C. Long reports on the medical aspects and the treatment of plague are included in the volume. The astonishing feature of some of these Government reports consists in the appointment of the editors. In this case at least one would have expected to see the name of a medical man rather than that of an officer in the Indian Staff Corps. Such a report would probably be best produced under the joint editorship of a plague expert and an experienced administrative officer. Apart from the expected report of the English Plague Commission it is time that the numerous reports from all parts of India were consolidated. There is now an immense waste of paper, while important observations get hidden away in small volumes.

The number of persons on famine relief continues to rise and now amounts to 5,600,000, being an increase of 123,000 on the returns of the previous week. The Central Provinces and Bombay Presidency are in the worst plight. The loss of human life has been extraordinarily small but the stock of cattle in some districts has been almost wiped out. An attempt is being made to transfer cattle from other areas, and 5000 have been ordered by the Bombay Government. The stock of wagons on the railways is so insufficient for the ordinary demands of trade that some difficulty will probably be found in conveying them. The present famine is far greater than any of its predecessors. This year water and fodder have failed as well as the crops, and over a wide area in the Punjab and Rajputana fodder has been absolutely unobtainable. Horses have been taken to other districts, but the cattle have been left to die and they have simply perished by hundreds of thousands.

May 10th.

PLAGUE IN AUSTRALIA.

(FROM A SPECIAL CORRESPONDENT.)

THE returns of plague in Sydney for the week ending April 21st show the following figures: remaining at the beginning of the week, 62; admitted, 16; died, eight; remaining at the end of the week, 70. The totals were as follows: admitted, 129; died, 46; discharged recovered, 13. Total "contacts" isolated, 719; cases among "contacts," five (see ante).[1]

The fall in new cases from the 23, 29, and 29 of the three preceding weeks to 16 during that under review has vastly cheered the popular mind and has even been the occasion of congratulatory paragraphs in the public press. This decline may stimulate to fresh exertions, and the rôle of Cassandra persistently played is not without its dangers for the impersonator. It is quite plain, however, that the disease continues to occur solely in relation to diseased rats, that the latter are far from having been killed off yet, and that cases come from localities further and further from

[1] THE LANCET, May 26th, 1900, p. 1548.

the original focus—which, notwithstanding the cleansing, still furnishes some. As Simond has said, the disease spreads like a spot of grease on paper. In four or five cases the patient, infected in the city, has fallen ill at a distance—in one case 140 miles away, in another 40 miles away, and in the remainder in suburbs about ten miles off--but these occurrences have been without consequences. The "contacts," of course, were inoculated in all these instances. It begins to appear that the medical officer of health is as helpless as anyone when the disease is not merely communicable directly but also originates with one kind of animal and spreads by the agency of another (or of other) animals. He may not and must not, derive comfort from the reflection that notwithstanding all that has been said and done in recent years epidemic plague has everywhere pursued its course, and has hardly been interfered with by the most strenuous efforts. A few small and solitary villages furnish the sole exceptions.

The mortality represented by the above figures, low as it is, represents a strictly "natural" mortality, for, as stated at first, it includes all deaths which occurred before admission to hospital and before any treatment had been applied. Were these deducted the hospital mortality (without further deduction for patients who died within 24 hours of admission) would probably not be above 30 per cent. For this result it appears that Dr. A. E. Salter, in charge, is to some extent directly responsible. His attention to the patients has been really unremitting, and probably several lives have been saved by his timely injections of five-minim doses of the pharmacopœial solution of strychnine beneath the skin; these he repeats every hour, two hours, or less often, till the imminent danger of death from failure of the heart has passed. To carry out treatment on this principle successfully the physician must be ever at hand. During next month consignments of Yersin serum are expected, one from the Pasteur Institute and another from the municipal laboratory at Messina (Dr. Terni and Dr. Bandi). They will be welcome, but the usefulness of treatment by this method can be judged only from the results attained in long series of cases; nothing, in the present writer's opinion, can be deduced from individual experiences. Plague is the most deceptive of all diseases. There is no member of the medical staff who has not had to admit again and again that patients have recovered whom he thought certain to die, and to die soon, and that others whom he thought in little danger have died within a few hours of his forming that opinion of their case. Calmette and Salimbeni have said something of the same sort as a warning not to refrain from injecting serum with a view to saving it for more urgent cases, for the latter cannot be distinguished with any certainty. A lengthened trial therefore is necessary.

The inter-colonial plague conference, after holding three meetings in Melbourne, concluded their deliberations at a fourth meeting held in Sydney. New South Wales could not, of course, be officially represented under these circumstances, but the meeting was held at the Department of Public Health and the chief medical officer of the Government was present by invitation. The members spent much time in the laboratories, visited the hospital, and visited quarantined areas in the city in order to make acquaintance with the methods of cleansing employed. This is a considerable business, estimated to cost not less than £30,000 a month in wages and material. The public gauge the return for this expenditure in loads of refuse removed and the like; they have not yet learned that it should be expressed in terms of rats. Nevertheless, rats are being killed in greater numbers than heretofore.

April 24th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Medical Benevolent Society.

THE seventy-eighth annual meeting of this society was held on May 23rd under the presidency of Mr. D. C. Lloyd Owen. The report read is of a very satisfactory kind and indicates the zeal and interest displayed in the society by the local officials. The invested funds now amount to £15,437, of which £6869 are invested in Birmingham corporation bonds and stocks. 16 annuitants were on the books at the beginning of the year. £467 had been expended in annual grants which ranged from £15 to £40. The number of members was then 384, 24 having been admitted during the year. The various officers were appointed and stress was laid upon the fact that so few members of the profession in the city and Midlands had joined the society, the advantages of which were so manifest. A dinner was subsequently held, at which a number of members and friends were present, and a pleasant evening was spent.

University of Birmingham.

The first meeting of the Court of Governors of the new university was held on May 1st. Mr. Chamberlain, as chancellor, presided. The Lord Mayor, Alderman Beale, was elected vice-chancellor and Alderman Clayton pro-vice-chancellor and treasurer. The first official act of the new chancellor was to invite the Court of Governors assembled under the authority of a Charter granted by the Queen to approve a loyal message congratulating Her Majesty upon the occupation of Johannesburg and Pretoria. The latter was a little premature, but subsequent events have realised the expectancy. Four members of the present Cabinet now hold the office of chancellor of a university. The energy and influence which Mr. Chamberlain has exercised in promoting the University of Birmingham have gone far towards developing this great scheme which is now an accomplished fact. The endowment fund now stands at £327,468. Although this sum exceeds the amount originally asked for it is now stated to be much below what is actually required, and another quarter of a million is sought. Time will show how far this great enterprise is to be a local or a national one, but if the hopes of its founders are to be realised a great and almost revolutionary model will be established to associate the progress of civil life with the industrial enterprise of a vast working community.

The Consultative Institution.

THE LANCET has already dealt in the issue of June 2nd with this subject in so far as it bears upon the medical profession and it remains to be seen how far the experiment will be successful or otherwise. The promoters express themselves as satisfied with the working of the first week and flatter themselves as to its ultimate result. The reasons adduced for the support of such a proceeding certainly do not appear sufficient to render it a justifiable one from a professional point of view. It is stated, for instance, that the class of people whom it is intended to benefit desire to have as a right what the profession would accord only as a favour, that is, in the diminution of a consulting fee to the sum of half-a-guinea. The questions of continued treatment, of operations, and of specialties, will become features which will involve much deliberation and care on the part of the promoters; the one medical gentleman who presides over the whole range of diseases and complications may find his position by no means an easy one.

June 5th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Horse Ambulances.

A DEPUTATION from the Medical Charities Committee of the city attended the meeting of the Watch Committee of the Manchester Corporation on May 24th to give reasons for the provision of horse ambulances. Mr. Alfred Simpson, chairman of the House Committee of the infirmary, said that in January last, on the advice of Professor D. J. Leech, the question was brought before the members of the Red Cross Society and a resolution was passed inviting the municipal authorities to provide horse ambulances and the resolution had been approved by the Sanitary Association of Manchester and Salford. Liverpool and other places in this country and various towns in America are far better provided as regards ambulance service than is Manchester. Mr. Alderman Rawson, chairman of the committee, assured the deputation that the committee were in sympathy with them and that a special sub-committee was already in existence for the purpose of considering the whole question. We may therefore hope that before long Manchester will not be thought lagging behind in the matter.

Manchester Water-supply.

At a meeting of the Waterworks Committee of the Manchester Corporation held on May 24th there was a discussion on the water-supply. The drought of last summer

put a considerable strain on the department. There has been no great rainfall since, and the demand for water increases so rapidly that the need for a larger supply is forcing itself more than ever upon the committee. An additional pipe two miles in length at Longdendale, to utilise flood water which now escapes, has already been decided on, but that will not meet the requirements of the near future. The committee, therefore, have decided to put before the Council the question of laying a second pipe from Thirlmere to Manchester. The cost is estimated at between £400,000 and £500,000.

Pollution of the Manchester Ship Canal.

The people of Grappenhall, through their parish council, have been praying the Cheshire County Council to deliver them from the grievous nuisance caused by the present condition of the Manchester Ship Canal, and have asked them to "take steps to abate the excessive obnoxious smells arising" from it. The vice-chairman of the Council (Mr. T. W. Killick) was not surprised that there was some annoyance at the delay in the purification of its waters. The Mersey and Irwell Joint Committee have been working for nine years with little apparent result, though it may be conceded that in some directions progress has been made—e.g., cinders and other solids are now kept out of the stream. The report of Mr. Tatton, the chief inspector, stated that "the manufacturers in the watershed had nearly all of them done their best to render their effluents innocuous. Considerable progress has been made in dealing with the local authorities, but it is not flattering to the self-complacency and tender sensitiveness of Manchester to hear that while some of the Cheshire authorities were behindhand in the work of purification "the winner of the wooden spoon was, of course, the Corporation of Manchester." A year ago the corporation was taken into court and Manchester was fined and promised "to amend its ways." The Rivers Committee of the Manchester Corporation have a sewage scheme, but it has not yet been sanctioned by the Local Government Board, and the Joint Committee are asking for a definite reply from the corporation "as to the steps they intended to take." Perhaps the court may see them again. But a faint hope was held out to the sufferers along the canal, for Mr. Killick thought there was "a possibility" that those who lived on the banks of the Manchester Ship Canal and its tributaries "would in the next year or two find a great reduction in the noxious smells of which the Grappenhall Parish Council complained." It seems a marvel that smells so strong and so vile can be produced, and a still greater marvel that they can be endured and that they kill so slowly.

June 1st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Royal Southern Hospital: Appointment of an Honorary Physician.

THE vacancy in the honorary staff of the Royal Southern Hospital caused by the retirement of Dr. John Cameron, the senior physician, has been filled by the appointment of Dr. Charles J. Macalister, physician to the Stanley Hospital. The elections to the honorary medical and surgical posts at the Royal Southern Hospital are carried out under the system which formerly prevailed at the Royal Infirmary and the Northern Hospital, where the electors comprised all subscribers of one guinea and upwards. In the case of the Royal Infirmary the limit was two guineas. Election committees, varying from 80 to 100 members, chosen from the subscribers at the annual meetings, have been established at the latter two hospitals and have been found to work in a most satisfactory manner. It is somewhat surprising that the Royal Southern Hospital has not followed the examples set by the Royal Infirmary and the Northern Hospital, where the old system was found to be both unwieldy and involving unnecessary expense to intending candidates. During the recent contest many subscribers to the funds of the Royal Southern Hospital took exception to being canvassed on behalf of the candidates, urging as a reason that they were not qualified to judge of the merits of the respective candidates and that the election ought to be in the hands of a special committee appointed by the subscribers for the purpose. I am informed that the electorate at the Royal Southern Hospital consists of about 1200 subscribers.

The Select Vestry and the Joint Committee on Tuberculosis.

At the last meeting of the select vestry four members were selected to serve until April 30th, 1901, on the joint committee for the provision, fitting up, furnishing, and maintenance of a hospital for the treatment of paupers suffering from tuberculosis pursuant to the order of the Local Government Board of April 5th, 1900. Miss Thorburn, one of the lady members of the select vestry, drew attention to the fact that as half the patients in the proposed hospital would be females the experiment would not be carried out under the most favourable circumstances unless the ladies were permitted to assist in the management of the hospital. She was not, however, now prepared to move an amendment to the proposed names inasmuch as the work of the committee for the next 12 months would be chiefly connected with buildings and matters in which ladies could not be of any particular assistance. She wished to give notice that on the occurrence of a vacancy on the committee later a lady would be proposed. The lady members of the select vestry have performed their duties as guardians of the poor in an unobtrusive and exemplary manner and it would appear that Miss Thorburn's request is a reasonable one to which no valid objection can be offered.

The Adulteration of Margarine and Cream with Boric Acid: Prosecutions at the Police Court.

The Liverpool stipendiary magistrate imposed a fine of £20 and £5 5*s*. costs upon a local tradesman for adulterating margarine with boric acid. On behalf of the prosecution Professor Boyce of University College said that the only interpretation he could put upon the quantity of boric acid used in the present case, which amounted to 0·73 per cent., or 51 grains to the pound, was that it was used to mask rancidity. Three medical gentlemen, together with Mr. Davies, an analyst, gave evidence for the defence to the effect that boric acid was not injurious to health, a theory which was strongly controverted by Professor Boyce, who had found from experiments upon kittens that boric acid when added to milk had produced in the animals violent diarrhœa and had caused emaciation. Mr. Stewart, in giving his decision, said it was sufficient for him that the introduction of boric acid was contrary to law. It was to the interest of the public to obtain a pure article, and it should not be possible to put on the market an article which otherwise could not be sold. Two other tradesmen were fined 20*s*. and costs each for adding boric acid to cream. In all three cases notices of appeal were given.

The Foul Atmosphere of the City Police-court.

The vitiated atmosphere of the Dale-street Police-court has been a constant source of complaint by magistrates and solicitors whose duties compel them to remain in the court for hours. Last week Mr. S. Quilliam, a solicitor practising in the court, addressed the bench on the subject and described the atmosphere as simply poisonous. The late Mr. T. Stamford Raffles, who had filled the post of stipendiary magistrate for a considerable number of years, bitterly complained of the foul air which he was compelled to breathe. The construction of the court must be seriously at fault so far as its ventilating properties are concerned, as the officials have done everything possible to keep the place ventilated with the means at their disposal.

A Liverpool Surgeon Wounded in South Africa.

Intelligence has reached Liverpool that Dr. R. Craig Dun, the honorary surgeon of the Children's Infirmary, who volunteered for the front and accompanied the 2nd Battalion of the Imperial Yeomanry as one of their medical officers, had been wounded at Draghoender, near Prieska. Happily, the wound received in the leg by Dr. Dun is not serious. His friends in Liverpool will be pleased to hear that the latest intelligence reports him to be progressing satisfactorily.

June 5th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Legacy to the Edinburgh Royal Infirmary.

THE late Mr. David Tinslie of Costerton, Mid Lothian, has by his will left the residue of his estate, after paying a few personal legacies, to his trustees to accumulate for 15 years, and thereafter to build, endow, and maintain with the

money a convalescent home in connexion with the Edinburgh Royal Infirmary. The residue of the estate, it is expected, will be worth between £200,000 and £300,000. He directs that the home should be named the "Astley-Ainslie Institution" in memory of his late nephew Mr. John Astley-Ainslie, son of the late Mr. John Ainslie of Huntington, East Lothian. The trustees are empowered to buy ground to an extent suitable for the hospital, with garden, policies, and recreation ground around it. It is also stipulated that the deeds necessary for the carrying out of this purpose shall be prepared by, or in the sight of, such person or persons as the judges of the Court of Session in either of its divisions shall appoint, and the deed has also to be submitted to, and approved of by, the Court.

Health and Sanitary Condition of Aberdeenshire.

The report for the year 1899, which has just been issued by Dr. James P. Watt, medical officer of the county of Aberdeen, shows that the total number of births registered in the eight districts of the county was 3431, or 28·3 of the estimated population (excluding burghs) of 121,260, while the total number of deaths reported was 1653, or 13·6 per 1000. The death-rate in the different districts, when calculated out, varied as follows:—Deer district, 15·1 per 1000; Ellon, 9·8; Garioch, 15·3; Deeside, 12·4; Turriff, 17·3; Aberdeen, 13·9; Alford, 12·8; and Huntly, 10·2. The mean temperature at the different meteorological stations, it may be mentioned, ranged from 43·5° to 47·0° F., and the rainfall for the year from 20·87 inches to 35·56 inches. During the year 814 cases were intimated under the Infectious Diseases (Notification) Act, 1889, as against 1019 for the previous year—viz: diphtheria, 122; erysipelas, 166; scarlet fever, 412; and enteric fever, 114. Of the 814 cases 300 were removed to hospital, there being now accommodation in all the districts. Of the 412 cases of scarlet fever reported (229 fewer than in the previous year) only three died, and there was no extensive outbreak of enteric fever, the cases happening either singly or in small groups. The drainage and water-works of all the villages are reported to be "good" or "fair," and scavenging has improved in all the districts except Aboyne, Torphins, and Braemar, where "nothing has as yet been done."

University of Aberdeen.

The Senatus having inquired into certain riotous proceedings by medical and other students at Marischal College on May 21st, during which Herr Hein, lecturer on German, was assaulted on account of supposed pro-Boer opinions, have reprimanded 16 students altogether, two of whom have also been fined 5 guineas each and three others 3 guineas each. The committee of the Senatus report that they strongly condemn the conduct of the students in their attack on a teacher of the University as being disgraceful and incapable of justification, and that such conduct should not be passed over without due punishment. At the same time the committee record their "desire to bear in mind that the students were actuated by a strong feeling of loyalty which made them resent in their own way what they regarded as an insult to Her Majesty, and that this feeling had been much intensified by recent events." Further, the Senatus, "having regard to the disorderly conduct of certain students at the recent graduation ceremony, has imposed modified fines of two guineas and one guinea on two students who were convicted of such conduct and of giving false names." The Senatus, it should be mentioned, disapproved of Herr Hein's conduct in the exhibition to his class of a cartoon disrespectful to the Queen. The general body of students have subscribed the fines imposed.

June 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

OWING to recent circumstances in connexion with the election of President the annual meeting for the choice of the new officers of the Royal College of Surgeons which took place on June 4th was viewed with more than usual interest. Mr T. Myles was elected President without opposition. Mr. L. H. Ormsby, surgeon to the Meath Hospital, and Mr. F. T. Heuston contested the vice-presidency, for which the former was elected by a considerable majority. The following is a list of the other officers of the College:—Honorary Secretary: Sir Charles Cameron, C.B. Council: Dr. A. H. Jacob, Sir Philip Smyly, Sir William Stokes, Mr. H. R. Swanzy, Mr. E. H. Bennett, Sir Charles Cameron, C.B., Dr. A. Meldon, D.L., Mr. C. B. Ball, Mr. R. L. Swan, Sir William Thomson, Mr. J. B. Story, Mr. J. Lentaigne, Mr. A. Chance, Mr. J. J. Cranny, Mr. R. D. Purefoy, Mr. H. G. Sherlock, Mr. R. B. McCausland, Mr. G. Stoker, and Mr. F. Conway Dwyer. It will be noted that some changes have taken place in the *personnel* of the Council. Mr. Graves Stoker is a new member of Council. Mr. William Stoker, who was a member of Council last year, recently accepted the post of Examiner in Surgery, while Mr. Conway Dwyer, who filled that examinership last session, has now become a member of Council.

Royal Medical Benevolent Fund Society of Ireland.

The annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held on June 4th at the Royal College of Physicians, Kildare-street. The chair was occupied by the President of the College, Sir John W. Moore, and there was a representative attendance to whom the report was submitted.

The Able-bodied Pauper.

One of the great blemishes of the Irish Poor-law system is the number of paupers all quite able to earn their own livelihood who crowd the workhouses. Some time ago it was decided to have a parade of able-bodied paupers residing in the Belfast workhouse, when it was found 600 were on the roll; now these have been reduced to 75, through the influence of the guardians getting them remunerative employment, and in part owing to the war. The number now are not sufficient to do the duties about the place, and it is proposed to give each man volunteering to work two ounces of tobacco weekly.

The Ulster (Benn) Eye, Ear, and Throat Hospital.

The twenty-ninth annual meeting of the supporters of this hospital was held in the board-room of that institution in Belfast on May 30th. In the report submitted it was stated that in 1899 there were 1704 patients treated in the hospital, and of these 286 were intern cases. The total receipts of the hospital from all sources amounted to £729 15*s.* 2*d.*, and the expenditure to £791 17*s.* 1*d.*, so that there is a loss on the working of the hospital for the year of £62 1*s.* 11*d.* The committee have decided to increase the charge per week for intern patients from 10*s.* to 15*s.* Were it not for the Benn endowment and building funds, which amounted to £8000, it would be impossible to keep the hospital going under an additional expense of £300 or £400 a year, so that the greatest care is taken to keep down expenditure in every department of the hospital.

The Typhoid Fever Epidemic in Belfast.

I regret to report the continued prevalence of typhoid fever in Belfast. It may for convenience be called an epidemic, but it is really simply an exaggerated condition of what unfortunately is now a normal condition in Belfast. Between April 22nd and May 19th 177 cases of typhoid fever were notified. As to the cause of the present outbreak it is most difficult to say. It would appear that the largest number of cases occurred in the neighbourhood of the Crumlin and Shankhill-roads (No. 3 and No. 10 districts), though the houses are comparatively recently built, generally in good sanitary condition on an elevated site, and the streets are wide and airy. The districts in Belfast which are most free from the disease are No. 1 and No. 5 (the Dock and Brown-square districts), and in these are some of the worst alleys and oldest houses in the city. This would seem to show that absence of fresh air and the presence of old and badly constructed houses have nothing to do with the present epidemic. Then, again, on the theory that the disease is water-borne it does seem strange why certain parts of the city are affected and not others supplied from the same source. Thus 19 out of the 57 cases notified last week occurred in Shankhill Ward. No wonder it was stated in the city corporation that the Public Health Department "was at its wit's end to find the cause of the outbreak of typhoid." Further, the state of the rivers and dams in the district is blamed by some as the cause of the outbreak and steps are being taken to make them clean. For the four weeks ending May 19th there were 64 deaths from zymotic disease, while in the corresponding period of last year there were 52. The death-rate from zymotic diseases was 2·3,

while the mortality from the same cause was for the corresponding period of 1899 only 1 9 per 1000. Scarlet fever is still prevalent, but as showing the mildness of this zymotic there have been no deaths. One of the Belfast papers calls special attention to the fact that the public officer of health reports that for the four weeks ending May 19th six cases of puerperal fever were notified. At the last weekly meeting of the Belfast Board of Guardians Dr. E. Coey Bigger, physician to the Fever Hospital, applied for additional temporary nurses, to cope with the increased number of typhoid fever patients who have recently been admitted. The present staff are overworked.

The Milk-Supply of the City of Belfast.

At a meeting of the City Council of Belfast on June 1st, Sir Otto Jaffe (ex-Lord Mayor) moved that it be an instruction to the Public Health Committee to collect information as to the supervision of the milk-supply in municipalities in the United Kingdom, America, and on the continent, particularly in regard to pasteurisation, &c., and that this information when collected be printed and furnished to the members of the council. There can be no question that in reference to the supervision of the milk-supplies of cities in the United Kingdom we are, with few exceptions, very much behind the municipalities on the continent and in America. There is here really no adequate supervision of the production of milk by boards of health such as prevails now in the majority of the States of North America, where authority is exercised in stamping out infectious disease prevalent among cows and in inducing a better management of cowhouses and dairies. In very few cities in the United Kingdom can certified milk be procured —that is, milk obtained from dairies where a committee consisting of physicians, pathologists, veterinary surgeons, and chemists certify after careful examination as to the general condition of the dairies. We are also far behind American cities in being able to obtain a supply of milk suited in its proportions to the different ages and digestive condition of infancy. Sir Otto Jaffe is moving in the right direction.

Irish Boards of Guardians and their Medical Officers.

The friction between the boards of guardians in Ireland and their officers—the dispensary doctors—still continues. Here are two recent cases:—Mr. J. J. Todd applied to the Omagh Board of Guardians for £3 3*s.* for acting as locumtenens for Mr. C. Hunter of Carrickmore who was subpœnaed to Dublin as a Crown witness. The board had refused to pay on the grounds that their medical officer should pay his own substitute, and the matter is now left to the Local Government Board to settle. At the meeting of the Omagh Guardians on June 2nd the chairman said he thought Mr. Todd was entitled to his money, but he alleged that an irregularity was committed by Mr. Hunter going off without any permission from the board of guardians or sanction of the Local Government Board. Mr. Hunter, however, replied that he acted strictly in accordance with the rules of the Local Government Board because in the face of a summons which said, "Fail not on your peril," it was not necessary to apply to the guardians. He had simply to apply to the relieving officer and he it was who appointed a substitute to do the work. It was decided to call the attention of the Local Government Board to the action of Mr. Hunter in leaving the district without the permission of the guardians. Again, in Ballymena, Mr. R. Currie, medical officer of health, applied to the guardians on June 2nd for leave of absence for seven days, nominating as his substitute Dr. W. R. Davison. Mr. Currie stated that he intended to apply for holidays later in the season. The guardians unanimously agreed that their board do not allow more than seven days as holidays to their dispensary medical officers in the year. Further, they decided to let Mr. Currie have the seven days on the understanding that these were all the holidays which they would give him this year unless he provided a substitute at his own expense, and they would only pay Dr. Davison at the rate of 2 guineas per week. All this unfortunate friction has arisen through the Local Government Board making a rule so ambiguous that its interpretation was doubtful. It is rumoured that in the course of the next ten days they will issue a new set of rules and in doing so they might remember a dictum laid down by the hero of Mafeking in his book "Aids to Scouting," which is as follows: "The secret of getting successful work out of your trained men lies in one nutshell—in the clearness of the instructions they receive." If the Local Government Board will simply state what is the length of the holidays for dispensary medical officers and what is the payment for their substitutes all this wrangle will cease. It is incumbent on them to make their rules clear and devoid of all ambiguity alike in the interests of the guardians and of their medical officers.

Charitable Bequests.

By the will of Mr. G. Washington Charters, who for a long time resided in Belfast, £5000 have been left to the endowment fund of the Royal Victoria Hospital and £1000 have been bequeathed to the Belfast Hospital for Sick Children.

June 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Solidarité Universitaire.

THERE has recently been founded, under the name of "Solidarité Universitaire Société d'Assistance Mutuelle des Étudiants Français et Étrangers," an association the aim of which is to assist students both past and present who have studied at higher educational establishments both in France and abroad but who are resident in Paris. The society proposes to find for its clients work suited to their particular form of study, such as translations, analyses of various works, bibliographical researches, *précis*, and similar work. The society comprises four classes of members—active members, givers of donations, founders, and honorary members. It is an interesting association and deserves encouragement.

Opening of the Pasteur Hospital.

A new hospital has just been opened in Paris under conditions which make a real landmark in the medical world. The actual official opening of the hospital has not taken place, for at present only one of the two blocks is in working order, but it is hoped that the other block will be ready by the month of July and that the foreign medical men attending the various Medical Congresses will be able to admire the hospital as a whole. The hospital is devised upon an altogether new plan and apparently is a realisation of the most perfect type of this kind of building at present existing. The funds necessary for its erection were offered to Pasteur some days before his death by an anonymous benefactor, and one of the last joys of that great man was to learn that a dream of his life was about to be fulfilled. The hospital stands in the rue Vaugirard, No. 213, upon a large plot of land facing the Pasteur Institute. That portion of the site which looks on to the rue Dutot is occupied by the great Institute of Biological Chemistry which was built out of a legacy left by the Baroness Hirsch and which is presided over by Professor Duclaux. The buildings of the new hospital are characterised by a feature all too uncommon in France—namely, a special fitness for the purpose for which they are intended. The architect is M. Florent Martin, a brother of Dr. Martin, assistant director of the Pasteur Institute, who, together with Dr. Roux, has given the minutest attention to all the details. The buildings consist of a number of isolated blocks connected by underground corridors. In the part looking on the rue de Vaugirard there is to the right a consultation block containing also quarters for the staff; to the right again is a small block destined for the lodging of the medical superintendent. In the middle of the site are two large blocks, identical in aspect, connected by a winter garden and a garden for the use of the patients. On the left the whole length of the site is occupied by a large block given over to general wards and disinfection rooms, while to the right at the back of the wards is an anatomical theatre. When a patient applies for entry to the hospital he goes through the consulting room into one of the six isolation rooms on the ground floor where he is examined by the medical officer who decides as to whether the malady is infectious or not. If it is the patient is shown into a special room called the *chambre d'entrée* and the isolation room out of which he goes is promptly disinfected. In the *chambre d'entrée* he strips completely and has a bath or a douche if there be no indication to the contrary. He then puts on hospital clothing and is put to bed in a bed which is wheeled or taken in a lift to another isolation room

in the block allotted to contagious cases. The *chambre d'entrée* is then disinfected and the patient's clothes are stoved. Each block contains 24 rooms with one bed, two wards for convalescents with 12 beds, and five wards with two beds each for such cases as where, for instance, the mother of a diphtheritic patient is unable to leave her child. In all, therefore, there are 53 beds. The floor of each ward is paved with stoneware tiles (*gré ceram*) and the walls also are covered to a height of 10 feet with tiles. The upper portions are glazed except on one side where the wall is double and contains all the pipes necessary for the supply of hot and cold water, hot air, ventilating tubes, gas pipes, and those in which the wires for the electric light run. By this means all the pipes can be easily got at while they do not show within the room. To each room there are two doors, one of which opens on to a central corridor and the other on to a balcony. By the latter the patient's wants are supplied when he is isolated completely. The furniture is very simple and comprises an iron bedstead and an iron table with a marble top. The air space of each room is 39 cubic metres instead of the regulation 30. If the patient is not considered infectious on his admission he goes to the usual consulting-rooms which comprise a medical officer's room, a room for surgical dressings, a bathroom, and three rooms with one bed each. There is also a little laboratory for clinical, chemical, and bacteriological examinations of urine, false membranes, and the like. As a whole the new hospital unites the isolation of the patient in its greatest degree with the greatest simplicity of procedure. The staff consists of one medical superintendent, one resident medical officer (*interne*), 17 sisters, a steward, and a manciple who looks after the catering. The medical superintendent, Dr. Martin, is, for the first time in a French hospital, supreme, except that he has once a year to send a report to the committee. Owing to this fact it is hoped that the usual differences of opinion between the medical officer and the director will no longer exist. The hospital will treat patients whether rich or poor gratuitously, they being admitted in the order of their applications as soon as there is a vacant bed. No serum therapy will be employed except with such sera as have already been established as of use. At present in the one block which is open only diphtheritic patients will be treated and persons bitten by mad animals who cannot be treated outside either because they are too poor or because they have developed hydrophobia during treatment. The opening ceremony was private, there being only present Madame Pasteur, the medical officers of the institute, the architects, and the workmen. After a luncheon the representatives of the press were conducted through the buildings and an oration was delivered by M. Duclaux.

Anti-alcoholic Measures in the Navy.

The Naval Minister has just decided to follow the example set by the Minister of War who, as I said in a previous letter, has absolutely forbidden the sale of drinks in barracks. M. Lanessan, however, has not been bold enough to go so far and instead of forbidding the sale of drink has contented himself with issuing edicts for its regulation. He recommends that all commanding officers should get rid of all drinks which are known to be harmful, such as absinthe and liquor known to be of inferior brands. The daily consumption is not to be above a certain maximum which will depend upon the number of the men on board and especially upon the number of time-expired men who have re-enlisted. These regulations are simply a farce and will produce no effect. The Minister has merely shirked his responsibility in face of the outcry of the Academy of Medicine and of those whom the enormous development of alcoholism in France rightly makes uneasy. Commanding officers cannot possibly brand any particular kind of drink as inferior without laying themselves open to an action for damages by the manufacturers. Finally, the recognition of the right of an old hand to toleration in this matter because he has contracted drinking habits abroad is ludicrous.

Treatment of Pneumonia by Brewers' Yeast.

Brewers' yeast which has given such good results in the treatment of furunculosis is undergoing the lot of all valuable drugs and is being gradually recommended for every disease. It is now many years ago that in France Dr. Backer, putting into practice the theories of Pasteur as regards infection by fermentation, brought forward what he called the medicine of ferments, and treated a great number of diseases by injecting under the skin pure cultures of brewers' yeast. According to him diabetes, cancer, and even tuberculosis were all amenable to this remedy. The researches of M. Brocq, which confirm those of many of the older physicians in the north of France, have shown that in brewers' yeast there exists a substance which exerts a specific influence upon tuberculosis, while M. Thiercelin has met with great success by its employment in the "green diarrhœa" of infants. Other trials have been made with this substance in the treatment of diabetes. At the meeting of the Hospitals Medical Society held on May 18th M. Marie related many successful instances of the employment of yeast in cases of ordinary pneumonia. He was led to try it owing to no preconceived theory, but purely empirically. M. Marie had under his care an old man, aged 68 years, who was not only suffering from a severe attack of pneumonia, but also from very grievous boils. To cure these last M. Marie prescribed yeast and was surprised to see that the pneumonia which he had thought would prove fatal immediately began to resolve. Thinking that this was a simple coincidence M. Marie treated seven other cases of pneumonia with yeast, and they all terminated favourably, the same result being obtained whether the pneumonia was lobar or lobular. M. Marie, however, considers that eight cases are not enough to form an opinion as to the value of the method since the disease in which it was tried often gets well of itself, and in any case the mortality is under 10 per cent. He considers, however, that the results are worthy of attention, for in four of the cases the prognosis was most grave, and there certainly seems to be something more than a simple coincidence.

June 5th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Trachoma in Switzerland.

DR. C. BAUER, Professor Haab's clinical assistant at Zürich, has written a report upon this disease, which is very rare in Switzerland. Out of 65,000 ophthalmic cases registered from 1862 to 1899 he could only find 153 cases. As 137 of these were foreigners, and those mostly Italians, there were only 16 cases of Swiss patients, some of whom had imported the illness. Owing to the influx of Italian workmen in the last few years to Zürich there were annually some 20 cases under treatment, as the 9000 Italian workmen formed a good percentage of the inhabitants of the town of Zürich, the population of which town was 165,000. The fact that these men congregate together and mix very little with the German-Swiss population explains why the cases of trachoma among the inhabitants have not increased. Prophylactic measures are, however, to be put into action to prevent any possible spread of this dangerous affection.

Iodine Preparations.

Professor Goll, lecturer on Pharmaceutics at the Zürich University, has published a *résumé* on this subject. He mentions the discovery of iodine by Courtois in 1811 and the publication of Cointet in 1820 on the treatment of goitre. Lugol in 1831 and Wallace in 1836 specially promoted the use of iodine in syphilitic affections. Acute iodism which occurs in 10 per cent. of all cases can sometimes be averted or the attack shortened by a daily dose of up to half an ounce of bicarbonate of soda. Professor Goll mentions the newest iodine preparations which can be employed with the slightest risk of iodism—the "eigons" containing from 14 to 20 per cent. of iodine in an albuminous form, the "iod-albacid" of Dr. Gans of Frankfort (10 per cent.), and the "iodipin" of Dr. Winternitz (Prague), an oily solution of execrable taste but of prompt action and therefore recommended for gluteal injections which are reported to be painless. In cases of tapeworm he advises a solution of three grains of iodine in 50 grains of iodide of potassium and four ounces of water in doses of from four to five tablespoonfuls a day.

School Hygiene.

The first meeting of the newly founded society for school hygiene, which counts many medical men among its members, will be held at Zürich on June 9th and 10th in connexion with a hygienic exhibition. There will be some

interesting lectures by competent medical men, sociologists, and hygienists on Destitution from a Medical Point of View, the Construction of Floors, Walls, and Ceilings in Schoolhouses, and the Results of Holiday Outings in the Mountains for Weakly School-children.

Zürich, May 30th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Mosquitoes and Malaria in Arabia.

Dr. Armand Ruffer and Dr. Innes have just returned from an excursion to Mount Sinai and in passing Wady Ferran to the north of Sinai the latter found the larvæ of an undetermined kind of anopheles which strictly resembles some previously found in malarial parts of Egypt. He heard from the Bedouin that many of the inhabitants of this Wady suffered from fever and he saw some of them with enlarged spleens. Moreover, the Bedouin told him that the mortality of the neighbourhood had only become great since 20 years ago, when the Wady was transformed into a marsh. This statement was borne out by the recent growth of the cemetery. Malaria and anopheles larvæ were also observed at Tor which is now full of pilgrims returning from the Hedjaz, some with small-pox and dysentery, but being on the whole singularly free from plague. The object of the expedition was achieved, which was to collect insects, snakes, lizards, birds, and small mammals for the British Museum.

Plague in 1853 and in 1900.

It has always been a wonder how it was that plague suddenly died out of Egypt in 1844 after being present every spring for 20 years. A thesis dated 1853 which has just fallen into my hands shows that the subsidence was much more gradual. The writer was a Frenchman, Dr. Cuny, who had lately served the Egyptian Government as chief sanitary inspector of Middle and Upper Egypt. He says that plague had never ceased to be endemic in Egypt, and that every year many sporadic cases were seen both in the Delta and on the Upper Nile. He cites one case out of many seen in Cairo in April, 1853. The disease is described as a fever occurring every spring always with swollen glands and rarely with abscesses, sometimes endangering life but more often so mild that patients could go back to their work after a few days' rest. In 1850 he saw plague in several villages and counted 10 cases in one village alone, but one of the Government vaccinators was nearly dismissed for putting his chief upon their track. The native doctor of Samalout excused himself for not reporting the existence of plague in a rich townsman by saying that he would certainly be assassinated if the dreaded land quarantine were imposed. Another native doctor under Dr. Cuny was dismissed from his post by the central authority because he had announced some cases of sporadic plague. The people buried their dead secretly in their houses, mosques, or churches, and feared more than the plague itself the quarantine measures and the insatiable avarice of the sanitary officials. It appears that Dr. Rossi at this time was dismissed from the Viceroy's service because he had reported a sporadic case of plague near Cairo, and this was by no means a unique case. Whether the disease existed in Egypt after 1853 I do not know, but there is at present no evidence of even sporadic cases between 1853 and 1898. Customs have now happily changed and the sanitary department of to-day is always reminding its officials that in the springtime plague must never be forgotten. At Port Said the total number of cases to date has been 30, of which 13 have been fatal, while at Alexandria there have so far been six cases including four deaths. The consular authorities in both towns are working well with the sanitary officials and there is now practically no obstruction among Europeans and natives, both of whom go willingly to hospital. Another satisfactory sign is that for some days there have been no deaths occurring outside the hospital and everything tends to show that the Port Said outbreak is being cleverly kept in check. The rubbish of all of the dirty houses in Port Said is being carted away in sacks to be burnt with petroleum, and an interesting proof of the value of this precaution has just occurred. One of the men in charge of the destructor, in spite of warnings, insisted on working with naked feet and legs. In a few days he was admitted to the plague hospital with typical inguinal buboes, apparently contracted directly from the rubbish. There have been some suspected patients in other parts of Egypt, but none have borne the test of examination. The three bacteriologists, Bitter, Symmers, and Gottschlich, are all busily employed in testing doubtful cases.

"Bulletin Quarantenaire de la Semaine."

Under this heading the quarantine department in Alexandria publishes every week all news relating to plague, cholera, yellow fever, cattle-plague, and foot-and-mouth disease. The information extends to many distant countries. Plague is reported from Jeddah, Lahidj in Arabia, Bombay, Calcutta, Karachi, Hong-Kong, Australia, Japan, Rio de Janeiro, and Buenos Ayres. Bombay and Calcutta alone are responsible for cholera, while yellow fever is known at Panama, Havana, Santos, Mexico, and Brazil. Of the returning pilgrims from the Hedjaz, 291 have now been treated at the Tor Hospital, of whom 107 died from *maladies ordinaires* and 184 were cured. The chief disease is dysentery.

Vaccination Institute.

The experiment tried for the first time this spring of re-vaccinating the adult population has succeeded well and crowds of natives have swarmed to the various sanitary officers to be protected from a disease which they all know and fear. More than 200,000 people have been operated on, mostly in Cairo. The institute continues to improve and to supply excellent lymph. The latter is now mixed in the following proportions—lymph, one part; glycerine, two parts; and water two parts. Better results have been attained since the pulp is passed twice through the crushing machine and since the tubes are regularly kept at a temperature of 60° F. Each buffalo calf provides sufficient lymph with economical management for vaccinations varying in number from 12,000 to 22,000.

Cairo, May 21st.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

IN Sydney the plague has become firmly established and the number of persons attacked continues daily to increase in spite of vigorous measures on the part of the health authorities. The total number of cases of plague reported up to April 27th was 151, and 53 patients have died. Of those who succumbed 13 died at their own homes, nine in the metropolitan hospitals, and the remainder in the quarantine hospital. All were interred in the quarantine grounds with due precautions. At the quarantine station are also isolated 262 persons who have been "in contact" with plague cases. Professor Anderson Stuart in a lecture delivered recently estimated that the plague would continue in Sydney for the next four months at least. It is stated that the expenditure incurred by the Government in dealing with the plague amounts to approximately £30,000 a month. The work of prevention and extermination consists in quarantining areas in the city wherever cases occur, chiefly round Darling Harbour, and then employing the quarantined labourers in clearing out the filth that has been accumulating in them for years. The dwellings of "contacts" are thoroughly disinfected, mostly by the "formalin" process, and all persons in any way associated with plague cases are detained in quarantine for five days. The Government distributes free a special rat poison to all householders and sends round men to remove dead rats from premises free of charge. Many houses have been condemned and pulled down. A special hospital has been equipped at the quarantine station and placed under the charge of Dr. A. E. Salter, formerly health officer at Thursday Island. The Government has also appointed Dr. Harvey, formerly a medical officer of the Peninsular and Oriental service, as an expert on the bubonic plague, he having had experience of the disease in India and the East. A capitation reward is given for rats and an immense number have been destroyed. In connexion with the mode of transmission of the disease Dr. Tidswell, the bacteriologist of the New South Wales Health Department, has confirmed the observations of Simond as to the part played by fleas, and has demonstrated the existence of plague bacilli in the alimentary canal of fleas taken from plague-affected rats. In all the colonies extermination of rats is being carried

on most vigorously. In Victoria steps are also taken to prevent the introduction of rats from other ports in vessels. Every vessel must be kept four feet away from the wharf and all pipes, ports, and scuttles closed. All gangways and ropes, &c., by which rats might get ashore are to be kept in a sticky condition with tar and a constant supervision maintained by special watchmen. A special staff is employed in inspecting and seeing that regulations are carried out, consisting of Dr. Elkington, two inspectors, and three assistant inspectors. Inoculations with Haffkine's serum are being freely employed. In Victoria two cases of plague have occurred, both on a vessel arriving from Sydney. The vessel was quarantined for 12 days and the patients were placed in tents at the station, under the charge of Dr. Bull, of the Public Health Department. Plans have been prepared for hospital buildings to be erected at Coode Island for the reception of possible plague patients, consisting of two wards for ten patients each and the necessary administrative buildings, a bacteriological laboratory, &c., and accommodation for "contacts" and "suspects," all isolated. The estimated cost is £19,000, and the Government is not prepared at present to sanction so large an outlay for buildings that may never be required. Dr. D. A. Gresswell, however, the President of the Victorian Board of Health, is of opinion that the plague is sure to break out in Victoria and that the buildings are wanted. Several cases have occurred at Fremantle in West Australia, and there has been one case at Rockhampton in Queensland. The precautions taken in all the colonies are practically the same. The Premier of Victoria convened a conference of health officials to draw up regulations for the prevention of the spread of the plague. The following were appointed members of the conference:—Dr. Gresswell (chairman); Dr. Ramsay Smith, President of the Central Board of Health, South Australia; Dr. Black, Government medical officer, Western Australia; Mr. Mault, secretary of the Central Board of Health, Tasmania, advised by Dr. G. Sprott and Dr. Holmes; and Dr. W. W. R. Love, secretary of the Board of Health, and Mr. C. J. H. Wray, Government quarantine medical officer for Queensland. The sittings commenced in Melbourne and extended over three days there, and then, as New South Wales was concerned in any decision which might be arrived at, the conference adjourned to Sydney.

The Sydney and Prince Alfred Hospitals.

A deputation representing the committees of management of the Sydney and Prince Alfred Hospitals waited on the New South Wales Treasurer recently to ask for further financial assistance. Both institutions were in debt. The public subscriptions were stationary, but the expenditure had increased, chiefly owing to increased cost of provisions. Each bed cost the hospitals 28*s*. per week, and the Government only allowed £1 per bed for Government patients. The Minister said he would lay the matter before his colleagues in such a way that he felt sure provision for the hospitals' requirements would be made in the estimates.

Victorian Branch of the British Medical Association.

A special meeting of the Victorian Branch of the British Medical Association has been held for the purpose of filling the vacancies on the council caused by the resignation of that body as previously reported. The attendance was very small. The following office-bearers were elected:—President: Dr. Neild. Vice-President: Mr. F. M. Harricks. Honorary treasurer: Dr. Mullen. Honorary secretary: Dr. W. B. Vance. Local editor: Dr. L. Henry. Council: Mr. F. G. Hamilton, Mr. G. Cuscaden, Mr. J. Cox, Dr. W. Macansh, Dr. T. R. H. Willis, Dr. C. P. W. Dyring, and Dr. R. E. Weigall.

Memorial Portrait of the late Sir Anthony Brownless, M.D.

On April 25th His Excellency the Lieutenant-Governor performed the ceremony of unveiling a memorial portrait of the late Sir Anthony Brownless at the Wilson Hall, Melbourne University. Few men have devoted themselves so unselfishly to the University as did Sir A. Brownless, who was connected with it for 42 years, first as Vice-Chancellor and afterwards as Chancellor, and was practically the founder of its medical school, and, as the governorsaid: "If any school in the University had done greater and more important service than another it was the medical school." The portrait represents Sir Anthony Brownless in his Chancellor's robes and is an admirable likeness.

April 28th.

Obituary.

CORRADO TOMMASI-CRUDELI.

(FROM AN ITALIAN CORRESPONDENT.)

AN eminent patriot and man of science has just been lost to Italy. The Senator Tommasi-Crudeli died on May 30th at his residence in Rome in his sixty-seventh year. Born at Pieve Santo Stefano, in the province of Arezzo, he devoted himself to the study of medicine first at Pisa, then at Florence, and finally at Paris, where he attended the cliniques of the great Parisian consultants, Trousseau and Léon Colin, till the outbreak of hostilities with Austria in 1859. He saw a good deal of active service with the "Cacciatori delle Alpi," a corps in which he was surgeon-lieutenant, and on the conclusion of peace returned to Florence, where he was appointed assistant lecturer in pathological anatomy at the Istituto di Studi Superiori. Next year (1860) witnessed Garibaldi's descent on Sicily and young Tommasi-Crudeli joined the expedition that followed it at the head of 800 Tuscan volunteers whom he had helped to organise. At Palermo he was nominated "capitano medico"; at Milazzo he was wounded, and at Faro di Messina, where he was by this time promoted major, he was again wounded at the head of his battalion. On the annexation of the Two Sicilies he resumed his professional work at Florence, retaining the rank of honorary major in the 77th Infantry and holding the medal for military valour. Three years thereafter (1863) he was nominated Extraordinary Professor of Pathological Anatomy at Florence (the chair to which he had acted as assistant) and in 1865, as the result of a competitive examination, he was appointed professor of the same subject in the University of Palermo. In the following year, memorable in Sicily for the cholera visitation and the popular tumults that accompanied it, he commanded a select corps of the National Guard of Palermo and helped to restore order while working fearlessly and effectively in combating the epidemic. On this he compiled a report embodying acute and independent views on the etiology and the favouring conditions of cholera—a document which was reprinted 18 years afterwards on the return of the epidemic in 1884. By this time his fame as a pathologist was well established and at the instance of the great mathematician, then Minister of Public Instruction, Francesco Brioschi, he was in 1870 called to Rome to start the Istituto Fisiologico e Patologico in connexion with the new university. This he shortly after converted into the Istituto Anatomico e Fisiologico, with its seat on the Viminal Hill, and brought it up to the high standard of efficiency it has since maintained. His skill as a demonstrator in the laboratory and a lecturer in the theatre drew crowds to his classes and led to his nomination as extraordinary member of the "Consiglio Superiore della Pubblica Istruzione." In 1874 he was returned to Parliament for the constituency of Cortona; was re-elected during successive legislative periods; and in the fifteenth of these he carried a Bill for the diminution of the salt tax in a speech which is still remembered as one of the most powerful vindications yet attempted in Italy of State Hygiene as a factor in the nation's well-being. His duties in Parliament, however, never interfered with his work in the Anatomico-Physiological Institute. Well known and appreciated in Germany, where he had many friends, he followed up his researches on diphtheria, conjointly with Huster of Greifswald, by further and yet more elaborate studies on malaria, this time in conjunction with Klebs of Prague. These, which were published at the expense of the Royal Academy of the Lincei at Rome, carried the solution of the problem a considerable step beyond Léon Colin and the French Commission of 1869, and undoubtedly prepared the yet further advance made in that direction by Laveran in France, by Golgi in Italy, and more recently by Manson and Ross in Great Britain, to say nothing of Grassi, Bignami, Dionisi, and others of his compatriots. His work on the Climate of Rome, which was reviewed in THE LANCET of Oct. 9th, 1886, p. 674, though requiring supplement as to its views on the etiology and propagation of malaria, is still consulted for its admirable account of the distributi on of subsoil water in the Campagna and for its demonstration of how malaria was practically non-existent in the second

century A.D. owing to the enlightened system of drainage and cultivation under the Antonines.

Other works still in repute among his compatriots are his "Istituzioni di Anatomia Patologica" and his "Preservazione dell' Uomo nei Paesi di Malaria colla Cura Arsenicale." In 1892 he was nominated Senator of the Kingdom of Italy, in which capacity he continued in the Upper Chamber the enlightened advocacy of State hygiene that won him so much respect and authority in the Lower. Of late years, though (comparatively speaking) by no means an old man, his work, scientific and legislative, sensibly slackened, the cause being a steady, if slow, failure of physical power due to the intense and often imprudent energy of his early manhood and middle age. For some months past he was seen by few except his intimate friends and medical colleagues till the end came on the evening of May 30th.

JAMES GROSVENOR MACKINLAY, F.R.C.S. EDIN.

MR. J. G. MACKINLAY, who died on May 24th at his residence, 15, Stratford-place, W., was born in 1844 at Isleworth. He was the eldest son of Dr. John Mackinlay, a surgeon in the Honourable East India Company's service from 1824 to 1834, and afterwards in practice at Isleworth for many years. He was educated at Epsom College and studied at Charing-cross Hospital, subsequently becoming house surgeon and for a few months holding the post of resident medical officer. On the somewhat sudden death of his father, in July, 1866, young Mackinlay was hastily called to give up his hospital appointment and take up the work thus vacated. His thoroughness in work and in the knowledge of his profession, combined with great kindliness of heart and absolute straightforwardness, enabled him to build up a capital practice and greatly endeared him to his patients. To the poorer classes he was a warm friend as well as a skilled adviser, and when a very serious attack of acute lung mischief compelled him hastily to throw up his practice in 1874 and (under the advice of the late Sir Andrew Clark and other medical friends) seek a doubtful restoration in the Antipodes his loss was greatly and truly mourned. Two years later, in much restored health, he re-commenced practice, but exchanged the wear-and-tear of general work for the study of the eye, which had had great attractions for him in his student days (he had been house surgeon to the Royal Westminster Ophthalmic Hospital in 1865). After filling the offices of registrar and clinical assistant to the last-named hospital he was appointed surgeon to the Western Ophthalmic Hospital, which post he held for five years. In 1879 he was elected ophthalmic surgeon to the Royal Eye Hospital and in 1881 to the Royal Free Hospital, both which appointments he held at the time of his decease. He was an Original Fellow and early a Member of Council of the Ophthalmological Society, to the Transactions of which he made numerous contributions, and for many years he was a member of the British Medical Association. His health had failed considerably during the past three or four years and for the last 12 months he had only on rare occasions been able to attend to any public or private work. By those who knew him intimately his memory will always be greatly cherished and his premature death sincerely mourned. He leaves a widow to deplore her loss.

AYLMER ELLIS HAYES, D.S.O., M.R.C.S. ENG., L.R.C.P. EDIN.

LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

LIEUTENANT-COLONEL AYLMER HAYES was the son of the late Captain Hayes of the 83rd Regiment. He entered St. Mary's Hospital as a student in 1865 and took the diploma of M.R.C.S. Eng. in 1871. After a short experience of general practice he joined the Army Medical Staff, becoming surgeon in 1877, surgeon-major in 1889, and lieutenant-colonel in 1897. He saw much hard service in India and in Egypt, going through the whole of the Afghan war in 1878–80 for which he was granted the medal. In the Soudan war of 1888–89 he was principal medical officer on the staff of the then Sirdar, Sir Francis Grenfell. He was twice mentioned in despatches for his gallant conduct in this campaign and in August, 1890, was invested by Her Majesty at Osborne with the D.S.O. for distinguished service before the enemy. He also gained the Egyptian medal with two clasps, the Khedive's star, and the 3rd Class of the Medjidie. He was afterwards registrar and secretary to the Surgeon-General at Netley Hospital, and from 1893 to 1895 was in command of the 2nd Station Hospital at Aldershot. His next term of service was at Hong-Kong, and in September, 1897, he retired from the active list. He was a distinguished student of Oriental languages, passing the higher standard of Persian and gaining the prize in Arabic open to officers of the army. When the present war broke out he rejoined the army in command of the Connaught Hospital, Aldershot, where he had the care of some hundreds of invalids from South Africa.

About February in this year he began to fail in health and in March there was no concealing from him that he was suffering from malignant disease of the œsophagus and that his end was near. He elected to continue his work, which became the more arduous as the number of invalids from South Africa increased and as day by day his powers of taking nourishment diminished. On May 14th, after discharging his duties for the last time, he came to London in too serious a condition to return and he died six days later. He was buried at Aldershot on May 24th with full military honours. Among those present were Surgeon-General T. F. O'Dwyer, principal medical officer, Brigade-Surgeon Wilson, Lieutenant-Colonel Knox, A.M.S., commanding the Cambridge Hospital, Colonel Leyden, Major James, Major G. Hale, D.S.O., Mr. Ernest Lane, and Dr. Sidney Phillips, who with Mr. Edmund Owen had attended him in his last illness. Lieutenant-Colonel Hayes was a born soldier and was devoted to the army and to his profession. He was an able surgeon, as already mentioned, an accomplished musician and an Oriental scholar. He had a fine physique and a handsome presence, and there were few men more full of wit, gaiety, and vivacity. His courage on the field of battle met with public acknowledgment, but it was not greater than the fortitude with which he concealed from those around him the nature of his last illness and with gradually failing strength struggled to the last to discharge the duties of his post.

JAMES FENTON STAMPER, M.D. ST. AND., M.R.C.S. ENG., L.S.A., J.P.

DR. JAMES FENTON STAMPER died at his residence at Pembroke Dock on May 22nd. The deceased, who had been for many years in practice at Pembroke Dock, received his medical education at Guy's Hospital. He took the qualifications of M.R.C.S. Eng. and L.S.A. in 1861 and graduated as M.D. at the University of St. Andrews in 1862. Dr. Stamper was consulting physician to the Pembrokeshire and Haverfordwest Infirmary and surgeon to the Pembroke Dispensary. He held several other appointments, being also Admiralty surgeon and agent. He was a justice of the peace for the borough of Pembroke. The funeral, which took place on May 26th, was attended by the mayor and corporation of Pembroke, the magistrates, ministers of religion, the members of the medical profession, and representatives of several public bodies.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of this society was held on May 30th, at 5 P.M., Mr. Christopher Heath was elected President, and he took the chair. Mr. W. H. Bennett and Mr. Manley Sims were elected Vice-presidents, and Mr. Borlase Hicks, Mr. Simmonds, Mr. L. Read, Mr. Julian Willis, Mr. Milburn, Dr. Buzzard, and Dr. Morison, to fill the vacancies in the Court of Directors; the other officers were re-elected. From the report read by the secretary it was shown that the grants during the year had amounted to £3007 10*s.*, while the expenses were £243 3*s.* 1*d.* The receipts available for payment had been £3353 7*s.* 7*d.*, and the grants and expenses £3250 13*s.* 1*d.*, leaving a balance of £102 14*s.* 6*d.* No legacy had been received during the year. 14 new members had been elected, 10 had died, and one had resigned. Three widows had been placed on the funds and two orphans, four widows had died and one orphan had become ineligible for further grants, leaving 49 widows and 11 orphans in receipt of grants. The death of Sir James Paget, President, was reported and of Mr. Mould, Vice-president. A grant of £26 under By-law 78 was made to a widow. A vote of thanks to the editors of the medical journals for their kind advocacy of the interests of the society was passed. Mr. Christopher Heath returned thanks for his election as President and the meeting closed.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, MAY 30TH.

THE Council met again to-day, Sir WILLIAM TURNER presiding.

Advertising by Medical Aid Associations.

Mr. BROWN moved:—

That the Registrar be instructed to send a copy of the resolution of the Council *re* medical aid associations of June 6th, 1899, to every registered medical practitioner residing in the United Kingdom.

This resolution, he said, had been come to in consequence of strong representations as to the injury being done to medical practice by the institution of medical aid associations which habitually employed canvassers to tout for patients. The terms of the resolution were "that the Council strongly disapproves of medical practitioners associating themselves with medical aid associations which systematically practise canvassing and advertising for the purpose of procuring patients." He was not aware that the passing of the resolution had had any great effect in checking the practices condemned by the Council, and, as members knew, when practitioners were brought before the Council to answer charges they very often pleaded ignorance of the regulations of the Council. He was very unwilling that any practitioner should be in ignorance as to the opinion of the Council with regard to this system of touting and canvassing.

Mr. HORSLEY seconded the motion.

Dr. HERON WATSON: Has Mr. Brown made any calculation as to what the cost of this will be?

The PRESIDENT: Have you looked into that matter, Mr. Brown?

Mr. BROWN: Perhaps the Registrar can give us some information.

The REGISTRAR (Mr. Allen) said that a circular in ordinary circumstances would cost £112, but as the Council would be sending out circulars next year to between 7000 and 8000 persons, the extra cost would be about £84.

The PRESIDENT explained to the Council that on more than one occasion this resolution had been sent out to individuals as a warning and information.

Dr. MCVAIL did not think the issue of this resolution would do much good. If the resolution had been stronger, if the Council had made up its mind to say that such conduct was infamous in a professional respect, then the case would have been different, but this was simply beating the air.

Mr. BRYANT said he did not think the Council would be prepared to go the length of saying that all such conduct was infamous conduct in a professional respect, though they might so regard particular cases.

Mr. BROWN insisted that this was a very pressing and important matter. He had just received a letter from the General Medical Practitioners' Union of Birmingham enclosing a copy of a pamphlet now in circulation, not touting for general practitioners, but touting for consulting practitioners. In this pamplet it was said that the ordinary medical man was only capable of dealing with the lesser ills of humanity.

The PRESIDENT said that the documents connected with this matter had reached the office of the Council and would be considered officially in due course; Mr. Brown might rest assured upon that point.

Mr. BROWN said he was glad to hear the statement of the President because he felt that the case was one which demanded consideration.

Sir JOHN BATTY TUKE suggested that Mr. Brown would gain his object by withdrawing his motion now and bringing up another one next session declaring these practices to be infamous conduct in a professional respect.

This suggestion was adopted by Mr. Brown and the motion consequently was withdrawn.

The Examinations of the Apothecaries' Hall of Dublin.

Sir DYCE DUCKWORTH presented reports from the Examination Committee on the examinations of the Apothecaries' Hall of Dublin held in October, 1899, January, 1900, and April, 1900. In the first report the committee said that the inspector reported that the examinations were in every way sufficient and he expressed his conviction that the body was doing its utmost to render them worthy of the confidence of the General Medical Council. In the second report the committee said the inspector reported that the examinations were in all respects sufficient. Speaking of the reports generally Sir Dyce Duckworth said they went to show that the examinations of the Hall were excellent. The inspector was satisfied with the conduct of them in all respects and made no adverse comments upon them. In the third report the Examination Committee said they desired to direct the attention of the Council to the fact that most of the candidates coming up for examination to this board had already passed the whole or parts of their previous examinations even in single subjects before other boards, sometimes in other divisions of the kingdom, and appeared either to choose or to seek by this piecemeal system admission to the Medical Register. This, of course, could not be regarded as satisfactory.

Mr. TICHBORNE took exception to this statement and asked Sir Dyce Duckworth as chairman of the committee to delete part of it.

Sir JOHN BATTY TUKE thought the whole statement should be deleted. The only point this Council had to consider was the statement that the examinations were in every respect sufficient.

Sir DYCE DUCKWORTH reminded members that this examination was the particular child of the Council and said the committee had been anxious to give the Council as much information as possible about it.

The Council by a majority decided to strike out the whole statement.

On the motion of Sir DYCE DUCKWORTH, seconded by Sir JOHN BATTY TUKE, it was agreed:—

That the Registrar be instructed to inquire of the various examining boards what evidence they require to be produced by candidates who claim to be exempted from examination in particular subjects on the ground that they had already passed in these subjects before other licensing bodies.

The Inspection of the Final Examinations.

Sir DYCE DUCKWORTH brought up the following recommendation from the Examination Committee, viz.:—

The Examination Committee desires to express its opinion to the General Medical Council that another cycle of inspections of the final examinations of the several universities and examining boards should be begun during the present year.

No inspection, he said, had been held for some seven years and it was thought by the committee that the time had come when they should begin another cycle of inspection. The committee had no proposal to make as to the division of the kingdom in which the inspection should begin. On the last occasion the arrangements were left in the hands of the Executive Committee. They would have to appoint an inspector and probably it would not be possible to get to work during the present year.

The PRESIDENT said it would take the Executive Committee some time to work out the details of the scheme.

Sir DYCE DUCKWORTH moved that the recommendation be received and entered on the minutes.

Dr. MCVAIL, seconding this motion, said it was about seven years since the last cycle of inspection ended. It began about 1887 or 1888 and it took five or six years for its completion. Under the Act they were supposed to be constantly inspecting the examinations and he quite thought the time had come when they should begin a new cycle of the final examinations.

Mr. HORSLEY: What is the probable cost

Sir DYCE DUCKWORTH: The average cost is about £360 a year.

Dr. GLOVER said he was disappointed with Sir Dyce Duckworth's way of putting this subject before the Council. The Council was not very flush of money just now and there was every reason why they should not spend money unnecessarily. If Sir Dyce Duckworth had shown any reason for believing that the effects of the last inspection had failed, or that there was anything seriously wrong in the way the examinations were conducted, or that a sufficient number of men were not being arrested by the examinations, he should not have offered any opposition; but in the absence of any such proof, or even an attempt to prove that the effect of the last supervision had passed away and that they were drifting into a loose or careless system of examination for admission to the Register, he could not think that any harm would be done by the postponement of this measure for

another year at least. He moved that there be a postponement for a year.

Dr. BRUCE seconded the proposal.

Dr. MACALISTER said that one reason for starting now was that it would be some time before the scheme could be got into working order. They could hardly get the first reports until 1901, which would be ten years after the last cycle was instituted. Another reason was that he regarded this not as a detective operation but rather as a stock-taking. It was right that the Council should from time to time discover what was going on. He had no doubt that this cycle of inspection, like the last, would disclose a great improvement in the examinations.

The motion for the receipt of the recommendation and its entry in the minutes was then put to the Council and agreed to.

Sir DYCE DUCKWORTH, seconded by Mr. BRYANT, moved:—

That, on the recommendation of the Examination Committee, arrangements be forthwith made by the Executive Committee under Chapter 23 of the Standing Orders for a systematic inspection and visitation of the final examinations of the several licensing bodies.

The proposal of Dr. Glover was put as an amendment and rejected by the Council by a large majority. Thereafter the motion of Sir DYCE DUCKWORTH was agreed to.

The Admission of Foreign Students to Examinations.

Sir JOHN BATTY TUKE presented the following report by the Education Committee on a motion seconded by Mr. HORSLEY, viz.:—

On Dec. 5th, 1899, it was moved by Mr. Horsley, seconded by Mr. Tomes, and agreed to:—

That the Education Committee be requested to consider the circumstances under which at present foreigners obtain exemption from some of the conditions of education and study required by certain of the qualifying medical corporations under the curriculum determined by the General Medical Council.

In the opinion of the committee this reference is covered by the "communication from the Education Committee in regard to the admission of foreigners to examination for registrable British qualifications," received by the Council on Dec. 4th, 1899. This communication stands as Appendix xvii. of vol. xxxvi. of the minutes.

This document sets forth clearly the conditions of education and study required of foreign students by the various qualifying bodies in Great Britain and Ireland and the committee deem it unnecessary to reproduce the statements therein made.

The Council has always held each licensing body as primarily responsible for the conditions under which it admits to examination candidates for its qualifications, and whenever reasons have existed for believing that the regulations were not in accord with the Council's resolutions the attention of the body has been directed to them. So far as the conditions of the various bodies regulating the admission of foreign students are concerned no specific case of inequality of conditions as between foreigners and British subjects has been brought under the notice of the Education Committee. Should any such representation on specific points be referred to the committee they are prepared to follow the usual course of sending the complaint to the body concerned, considering its reply, and reporting on the question to the Council.

The report was received, entered in the minutes, and adopted.

Diplomas in Public Health.

Mr. TEALE read the following interim report from the Public Health Committee dated May 28th:—

The committee cannot meet without expressing their sense of the great loss sustained by the Council, but above all by the Public Health Committee, in the death of their most able and indefatigable chairman, Sir Richard Thorne.

The committee have considered the replies of the bodies which confer diplomas in public health, with observations on the recommendations of the Public Health Committee contained in their report of Dec. 5th, 1899. Many of these replies contain carefully reasoned criticisms or suggestions demanding serious consideration, for which the Council is greatly indebted to those bodies. These criticisms and suggestions and the question whether the recommendations in the report of the Public Health Committee should need modification require more time than it has been possible to devote to their discussion during the present session.

The committee therefore recommend that the question should again be remitted to the committee for a final report at the November session of the Council. T. PRIDGIN TEALE, Chairman.

On the motion of Mr. TEALE, seconded by Dr. MCVAIL, this report was received and entered on the minutes, and the recommendation contained in it was approved of.

Registration of Students.

Sir DYCE DUCKWORTH presented a report from the Students' Registration Committee and moved that it be received and entered on the minutes and adopted. He remarked that the various cases mentioned in it had been very carefully considered. The decisions arrived at had been in most cases based on precedent and special consideration had been given to such cases as presented any special difficulty.

Dr. BENNETT seconded and the motion was agreed to.

Companies Act Amendment Bill.

Mr. TOMES gave in a report from the Committee on the Companies Act Amendment Bill. This informed the Council that Clause 3 of the measure now before Parliament dealt with the practice of medicine and dentistry by companies. The Bill had repeatedly stood on the order paper for second reading, but no further progress had been made with it, and it now seemed doubtful whether the Government intended to proceed with it during the present session.

The report was received and entered on the minutes, the motion acted upon being made by Mr. TOMES and seconded by Mr. HORSLEY.

An Application for Registration.

On the motion of Sir DYCE DUCKWORTH, seconded by Dr. MACALISTER, it was resolved to adopt a recommendation by the English Branch Council to enter on the Medical Register the name of Mr. William Raitt Scroggie, who holds the qualifications of Mem. R. Coll. Surg. Eng. 1882, Lic. R. Coll. Phys. Edin. 1882, Lic. Midwif. K. Q. Coll. Phys. Irel. 1882, a practitioner entitled to be registered under the Medical Act 1858, but who neglected to effect such registration until after the coming into operation of the Medical Act 1886.

Penal Clauses of Medical and Dentists Acts.

Dr. GLOVER asked leave to withdraw the following notice of motion which he had put upon the programme of business:—

That the Executive Committee, under the remit of resolution 13 in the minutes of May 24th, 1900, be requested to procure the written opinion of Mr. Muir Mackenzie as to the difference between Clause xxix. of the Medical Act (1858) and Clause xiii. of the Dentists Act (1878), with special reference to the obligation of the Council, under the respective Acts, to order the erasure of the name and qualifications of a practitioner, evidence of whose conviction for some offence has been supplied, or who has been found, after due inquiry, guilty of infamous conduct by the General Medical Council.

He (Dr. Glover) said that the necessity for this motion had ceased because it had been anticipated by the action of the Executive Committee.

Dr. PAYNE, who had agreed to second the motion, assented, and leave was given to withdraw the notice.

Advertising by Dentists.

Sir DYCE DUCKWORTH moved that a copy of the following resolution in respect of advertising adopted by the General Medical Council on May 20th, 1894, be issued from the Council's office to every dentist whose name is on the Dentists Register:—

That the attention of the Council having been called to the practice of advertising by certain dentists it is hereby resolved: "That the issue of advertisements of an objectionable character, and especially of such as contain either claims of superiority over other practitioners or depreciation of them, may easily be carried so far as to constitute infamous or disgraceful conduct in a professional respect."

In support of his proposal Sir Dyce Duckworth said that he had been moved to recommend this course to the Council because during the present session they had been told by persons who had been before the Council that they were really not aware of what the Council had done and therefore it seemed absolutely necessary to send their resolution of 1894 to every practitioner on the Dentists Register so that there might be no mistake in the future.

Mr. TOMES seconded the motion.

Dr. LOMBE ATTHILL said that the resolution seemed to sanction advertising generally and the Council disapproved of that. The four words "of an objectionable character" ought to be left out.

Dr. MACALISTER: That is the resolution.

Dr. LOMBE ATTHILL: Well, it will be brought up as a clear proof that advertising is sanctioned by this Council because it is only advertising of an objectionable character that we seem to disapprove of. I understood that we were to put down all advertising.

Dr. MACALISTER: I do not think that unobjectionable advertising could be called infamous conduct.

Mr. HORSLEY: That is not the point. Can we not amend the resolution as suggested by Dr. Lombe Atthill?

Mr. BROWN: That could scarcely be done without rescinding the resolution of 1894 and passing a new resolution.

The PRESIDENT reminded the Council that it was six years since the resolution was passed. He remembered very well the discussion which took place in connexion with it. The general opinion at the time was that the Council could not pass a resolution forbidding all forms of advertising and so the words "of an objectionable character" were inserted so as to show that there was a certain class of advertising

that the Council were not prepared to say was objectionable. Of course, if the Council's mind had changed during these six years, and they were now prepared to make their views more definite and more distinct, what he suggested was that they should not refer to the resolution of 1894 but pass another resolution. That really was the question that the Council had now to determine. If they passed Sir Dyce Duckworth's motion they practically adopted the old resolution of 1894, which they apparently did not think strict enough.

Dr. MACALISTER: We could not immediately proceed to act upon a new crime of this sort. We would have to give four or five years' notice.

Mr. TOMES: We have just acted for the first time on this resolution during the present session, and however desirable it might be to amend it the present is not an opportune moment for doing so.

Mr. HORSLEY: Would it not be better to withdraw this motion for the present and wait until times have changed a little more?

The PRESIDENT: It is for the Council to decide what is or is not objectionable.

Mr. TOMES: In medical cases it is the same—the Council have to decide.

Dr. MCVAIL: I think we should not proceed with this matter at all. It is tantamount to saying that advertising is objectionable. We should deal with cases as they come up, just as has been done this session.

The PRESIDENT: I think the ground for bringing forward the motion is that when we went into a case of objectionable advertising the other day it came out that this resolution of 1894 had never been communicated to persons on the Dentists Register, that it had been communicated only to some individuals, and not sent by post to every registered dentist. Sir Dyce Duckworth wants every dentist to have this put into his hands so that he might not have the opportunity of saying that he did not know of the resolution.

The motion was carried by 13 votes to 8.

Sir DYCE DUCKWORTH stated that the cost of giving effect to it would be about £17.

The Standard of Preliminary Examinations.

On the motion of Sir JOHN BATTY TUKE, seconded by Dr. MACALISTER, a further report of the Education Committee on the question of raising the standard of preliminary examinations in general education was received and entered on the minutes. This report was as follows:—

The Education Committee, in pursuance of the Council's resolution of Dec. 5th, 1899, have obtained from Mr. Sharpe, Dr. McGrath, and Professor McCormick a joint report "setting out in full their reasons for the conclusion they have arrived at with regard to the adoption of the senior and higher grade standard of preliminary education," together with a separate report from each of these experts on special points connected with the examinations of his division of the United Kingdom.

These four documents show that ample grounds are given for the conclusion that it is impracticable in the existing conditions to require of all intending medical and dental students the standard of general attainments represented by the so-called senior and higher grade examinations.

A substantial advance on the present requirements can, however, be made by insisting on improvements in the character and stringency of those "junior" examinations which can be directly influenced by the Council, and in the case of the others by requiring that candidates offering the corresponding certificates have obtained a higher standard than that of a simple pass.

Detailed suggestions are offered which, if adopted, would have the effect of bringing about the desired advance; and the committee, having considered these suggestions and discussed them with Professor McCormick, beg leave to commend them to the favourable consideration of the Council.

During the discussion a question, which has an important bearing on the problem in hand, was raised, and it appears to demand a definite answer on the part of the Council. The question is whether the time has not come for fixing a limit of age below which an applicant shall not be allowed to be registered as a medical or dental student. The committee are of opinion that such a limit should be fixed and propose that for the present an applicant for registration should be required to have attained the age of 16. At a future time, when a sufficient advance has been made in the standard of preliminary education, it may be advisable to raise the limit of age to 17. This would have the effect of inducing those who intend to enter on the study of medicine to spend a longer time over ordinary school subjects and so to fit themselves for the more stringent leaving and other preliminary examinations it is proposed to require. The committee accordingly recommend:—

1. That from and after Jan. 1st, 1902, no person shall be registered as a medical or dental student who has not attained the age of 16 years; and that for the purpose of ensuring the observance of this regulation every applicant for registration in the *Students Registers* shall be required to produce satisfactory evidence that this age has been attained.

2. That the Education Committee be authorised to take all needful steps to give effect to the recommendations and suggestions for the improvement of preliminary examinations contained in the appended joint-report of the expert advisers and to report from time to time to the Council thereupon.

The joint-report of Mr. Sharpe, Dr. McGrath, and Professor McCormick concludes with the following recommendations, submitted for the consideration of the General Medical Council:—

I.—THE CHARACTER OF THE EXAMINATION.

(*a*) In languages each examination should be of not less than two hours' duration, and if it includes questions on prescribed books (except in the case of prescribed masterpieces in English literature) of not less than three hours' duration.

In mathematics (which should include arithmetic, algebra, and geometry) the examination should be of not less than three hours' duration.

(*b*) In each examination the questions should be such as to test not merely knowledge but a power of intelligent application of knowledge.

In English the paper should include an essay and a paraphrase (see p. 14 (4)), also questions testing a knowledge of grammar, English history, and geography.

In classics and modern languages each paper should include at least one passage of some length from an unprescribed book for translation into English, an English passage of some length (except in Greek) and a few short idiomatic English sentences for translation, and questions on grammar.

In arithmetic and algebra most of the questions and problems should involve some thought and intelligent knowledge of the principles underlying the rules. In geometry most, if not all, questions should include a simple rider as an essential part.

(*c*) In languages questions on prescribed books should form not more than a third of the paper.

II.—THE DISTRIBUTION OF MARKS.

In English not less than a third of the marks should be allotted to the essay and paraphrase.

In classics and modern languages not more than a third of the marks should be allotted to questions on prescribed books, and at least a half of the marks should be allotted to "unseen" translation and prose composition.

In arithmetic and algebra the allotment of the marks among the questions should be, as far as possible, proportional to their difficulty. In geometry at least about half marks should be assigned to the simple rider attached to each book-question.

III.—THE STANDARD OF MARKING.

All examinations should satisfy the General Medical Council, by such supervision and organisation as may seem to them practicable, that the marking of examiners is conducted with due stringency and accuracy and is adjusted to the standard at which the examination aims.

IV.—THE MINIMUM PERCENTAGE OF PASS.

The *minimum* percentage demanded by the General Medical Council should be 40 per cent. in each subject (see IX.).

V.—THE MINIMUM STANDARD AT WHICH THE EXAMINATION SHOULD AIM.

In each subject the minimum standard and range of questions should approximate as nearly as possible to the standard and range of questions in the papers of the Lower Grade Leaving Certificate Examination of the Scotch Education Department.

It is suggested that the above proposals (I.–V.) should be regarded as instructions for all examining bodies and examinations at present recognised by the General Medical Council, except those of Government and University bodies, and that they should come into force, so far as these examining bodies and examinations are concerned, on Jan. 1st, 1902.

It is further suggested that the above proposals be sent to the above-mentioned Government and University examining bodies, together with the present report, if approved by the General Medical Council, and such portions of the confidential reports as the Education Committee may deem necessary in each case; and that these bodies be requested to state how far in their opinion their respective examinations meet the requirements of the above proposals, and how far it would be desirable or possible for them to make modifications in their examinations to that end.

VI.—Subject to the proviso of Recommendation IX., in the undermentioned examinations the pass-mark in each subject for the purposes of medical preliminary examination should, on and after Jan. 1st, 1902, be fixed as follows:—

University of Oxford Junior Local Examinations (honours standard in one or more subjects).
University of Cambridge Junior Local Examinations (honours standard in one or more subjects).
Oxford and Cambridge Schools Examination Board Lower Certificate Examinations, 40 per cent.
Central Welsh Board Senior Certificate Examinations, 40 per cent.
Scotch Education Department Lower Grade Leaving Certificate Examinations, 40 per cent.
Intermediate Education Board of Ireland Middle Grade Examinations, 30 per cent.

VII.—In the following examinations each of the four subjects may be passed separately:—

University of Oxford Senior Local Examinations (with distinction).
University of Cambridge Senior Local Examinations (with distinction).
Oxford and Cambridge Schools Examination Board Higher Certificate Examinations (with distinction).
Scotch Education Department Higher Grade, or Honours, Leaving Certificate Examinations.
Intermediate Education Board of Ireland Senior Grade Examinations (with distinction).

VIII.—In all examinations recognised by the General Medical Council other than those mentioned under Section VII. the examination in all four subjects must be passed at one examination or at not more than two examinations, provided that the candidate may offer himself for re-examination as often as may be necessary to satisfy this condition.

IX.—In the case of examinations which satisfy the requirements in Sections I.-V., when the four subjects are taken at one time the four parts may be regarded as one examination and a pass may be granted if the candidate reach the necessary percentage in the aggregate marks of his papers as a whole, provided that the required pass-mark must be reached in the English paper.

Sir JOHN BATTY TUKE, as chairman of the Education Committee, thought that before moving the recommendations of the committee he should run over the history of the movement for the benefit especially of those members who had but recently joined the Council. He said that almost immediately after its inception the Council directed attention to the subject of the preliminary examinations in general education, and the records of the Council bore testimony to the great interest which had been taken in it throughout. The first important result obtained was an improvement in the character of the examinations by the withdrawal from licensing bodies of their examinations in general education, and by their placing them in the hands of strictly educational bodies. The next important step was the laying down of requirements in the various subjects of examination. The Education Committee watched most carefully how their recommendations were observed and the effect was a gradual raising of the general standard. Subsequently the Council insisted upon greater stringency by directing that most of the preliminary examinations should be taken at one time. This was an important step forward as it got rid of two classes of candidates—the undesirable and the doubtful. The effect was very seriously felt by both schoolmasters and examining bodies, but perhaps the very success of the Council's action induced certain members to propose the very bold step of cutting out all junior examinations whatsoever. At the first blush this seemed an effective method of dealing with the subject, but on careful investigation by the committee it was found that it could not be adopted because it was surrounded by difficulties that were insuperable, the chief difficulty being the defective condition of intermediate education throughout the kingdom. There was a great gap between "lower junior" and "higher senior," and the very highest authorities, men who had the best knowledge of the subject, advised the committee that the difficulties were not such as could be overcome, and if it were attempted to adopt the scheme the most serious consequences would result to the profession and to the public. The Council, however, were not convinced and a *referendum* was ordered. The committee consulted heads of schools and colleges, various medical bodies, and a number of private individuals, and the result was that there was an overwhelming consensus of opinion that the committee's view was the correct one, and the main reason assigned was that the state of intermediate education would not permit of the adoption of the scheme. Therefore, the committee had suggested the appointments of three educational experts, whom it was hoped and believed were thoroughly representative of the different parts of the United Kingdom and thoroughly well acquainted with the condition of education within them. These gentlemen began their work about a year ago and it was necessarily very arduous work, and notwithstanding the time and attention they gave to it they were unable to produce more than a provisional report for consideration in November last. The Council naturally wanted more information on the subject and these experts were re-appointed and asked to prepare a full detailed report. They had done so, and he thought no one could say that it failed in presenting the position in a thorough and full manner, for it was a very carefully prepared document, a valuable treatise on the whole subject. The leading fact these experts presented was again the imperfect state of intermediate education. It might be said to be very sad that it should be so, but he might ask if they were very much worse off than any other country? He thought that the answer to the question was furnished in the experts' report. They said:—

We found that a preliminary examination which would demand the Scottish higher grade leaving certificates in the four subjects required by the General Medical Council would be of a standard much higher than that of preliminary or matriculation examinations in any faculty of any university with which we are acquainted.

Further, he thought experience showed that they were not in any worse plight than any foreign country, for it was found that the ordinary practitioners of, say, France and Germany were not of higher culture than their own men. He for one failed to meet a want of culture in their own men. Perhaps they were not scholars, but scholarship was not their business, and he thought that those who had impressed upon the Council the raising of the standard of general education higher had overlooked the fact that medical education was a liberal education in itself. It must be borne in mind that the medical student was brought into contact with subjects that required a large amount of collateral education and that his general education did not cease when he commenced the medical curriculum. His scientific course was as productive of culture as the literary training of the arts school. The experts concurred in the view of the Education Committee. They had adopted in their report the general principles that the Council should insist upon a gradual improvement of general education examinations. In point of fact, they recommended a standard of examination which might be roughly taken to represent the meeting-place of the higher juniors and the lower seniors, a grade which also represented the standard applied by the great examining bodies and conformed to the test of 16 to 17 years as being the suitable age for youths to enter upon scientific work. Certain people had held that uniformity could be best obtained by the Council instituting examinations of its own. But it would be *ultra vires* to do that and it would not, if it could be done competently, be advisable to proceed with such examinations because of the serious complications such a system would cause in relation to school examinations. But as a matter of fact the committee and the experts were content to work with the machinery which at present existed, and the experts had suggested a scheme by which the standard of present examinations might be raised and equalised, whether by higher pass marks or otherwise, and that these examinations should be allowed to be passed at not more than two times. The committee proposed that the suggestions of the experts should be sent to all university bodies with a request to know how far the general recommendations meet with their approval in theory and practice. They proposed also to send the opinions of the experts to a number of outside bodies who were not Government bodies or universities, in order that they might adapt themselves to the lines of the standard selected. The committee would have every opportunity of judging how far these bodies might conform, for they could see the set papers and examine the students' answers. With regard to the experts' conclusions, these had been arrived at to a very great extent from information contained in confidential communications. They said in their joint report:—

Much of the information upon which we base our classification is of a confidential character and has been obtained from the various authorities on this strict understanding. The points we have had to take into consideration are many and various, and merely to give a classification without our reasons for such classification would be of little or no service and might in many cases be misleading. In the case of a few examinations we have been unable, owing to insufficient information, to give more than a tentative estimate. Apart from these considerations public criticism of particular examinations might alienate some of those examining bodies upon whose cordial coöperation the General Medical Council must depend in bringing about a genuine reform. And, lastly, the scheme of reform which we have to suggest does not, at least for the present, necessitate such public criticism.

Accordingly he (Sir John Tuke) hoped that no demand would be made for the production of these confidential documents. He believed that if the Council agreed to the two recommendations which the committee proposed they would find that they had got a good and solid ground on which to build up future reforms. The committee asked the Council to have confidence in them and commission them to carry out the scheme as detailed in the experts' report. If the Council gave this commission the committee would keep in mind the strong desire on the part of the Council as well as of themselves to raise the whole character of these preliminary examinations, keeping in view the necessities of the public and the interests of the profession. He begged to move that the committee's first recommendation be adopted.

Dr. MACALISTER seconded the motion, because the experts told the Council that unless they decided that the age should be 16 years or below 16 their advice would be ambiguous. If it were 16 they gave clear directions as to what to do. The Council should therefore first settle the age and do that now.

Sir DYCE DUCKWORTH said that the feeling that prevailed in the Council was that they must take things as they found them and accept small mercies when they were offered, but he hoped that the Council would give expression to the view that the age might very soon be raised to 17 years.

Dr. LOMBE ATTHILL pointed out that if the age was raised higher than 16 that would not be convenient, for the Act provided for the registration of medical practitioners at the age of 21.

The motion was agreed to.

Accordingly, from and after Jan. 1st, 1902, no person shall
